

# SUPER PRECISION BEARINGS

## Introduction

As technologies evolve, all manufacturers share a global responsibility to respect and protect the environment. NSK Motion and Control products reflect our corporate commitment to environmental responsibility. While our products improve the performance of machines in a variety of industries, they also save energy and conserve resources because of our superior precision machining technologies.

To meet the needs of the highly specialized machine tool industry, we have enhanced each and every aspect of our R&D capabilities at our Technology Centers. Therefore, NSK's precision bearings are used in a wide variety of industries, such as semiconductor production and industrial robots, and have earned a reputation for excellent performance. Today, NSK manufactures highly accurate, reliable precision bearings in Japan and Europe and supplies them all over the world.

This catalog explains technical materials including our latest research and experimental data, various applications, the types of precision bearings available, and the proper utilization of each specific type of NSK's precision bearing.

Part1. NSK Super Precision Bearings

Global Support Capabilities	P6
Development Capabilities	P8
Quality Control and Production Capabilities	P10

Part2. Features of Precision Bearings

Metallurgical Technology to Extend Bearing Life	P14
Ceramic Rolling Elements	P16
Cages	P18
Bearing Components	P20
Product Range	P22
Performance of Each Bearing Type	P24

Part3. Selecting the Right Bearing is Critical

Bearing Selection	P36
Typical High-Speed Main Shaft Spindle Structures	P38
Other Spindle Structures	P40
Features of Angular Contact Ball Bearings	P42
Features of Cylindrical Roller Bearings	P44

Part4. Bearing Types

<b>1. Angular Contact Ball Bearings</b>	
High Precision Angular Contact Ball Bearings (Standard Series)	P48-60
Features	
Numbering System	
Bearing Tables	
Miniature Series, BSA Series for Ball Screw Support	
79 Series	
70 Series	
72 Series	
Ultra High-Speed Angular Contact Ball Bearings (ROBUST Series)	P62-79
Features	
Numbering System

BNR19, BER19 Series	
BNR10, BER10 Series	
BNR19XE/10XE, BER19XE/10XE Series (Spinshot™ II)	
BNR29, BER29 Series (Wide Series)	
BNR20, BER20 Series (Wide Series)	
Ultra High Precision Angular Contact Ball Bearings (ROBUST Series-BGR)	P80-84
Features	
Numbering System	
Bearing Tables	
BGR19 Series	
BGR10 Series	
BGR02 Series	
<b>2. Cylindrical Roller Bearings</b>	
Cylindrical Roller Bearings	P88-97
Features	
Numbering System	
Bearing Tables	
Double-Row Cylindrical Roller Bearings (High Rigidity Series)	
30 Series	
39 Series	
49 Series	
Single-Row Cylindrical Roller Bearings (Standard Series)	
10 Series	
Ultra High-Speed Single-Row Cylindrical Roller Bearings (ROBUST Series)	
10 Series	
Double-Row Cylindrical Roller Bearings (Low Heat Generation Series)	
30 Series	
Ultra High-Speed Single-Row Cylindrical Roller Bearings (Low Heat Generation Series)	
10 Series	
<b>3. Angular Contact Thrust Ball Bearings</b>	
Angular Contact Thrust Ball Bearings	P100-105
Features	
Numbering System	
Bearing Tables	
High-Speed Angular Contact Thrust Ball Bearings (ROBUST Series)	
BAR10 Series	
BTR10 Series	
Double-Direction Angular Contact Thrust Ball Bearings (TAC Series)	
TAC29D Series	
TAC20D Series	
<b>4. Ball Screw Support Bearings</b>	
Angular Contact Thrust Ball Bearings for Ball Screw Support	P108-113
Features	
Numbering System	
Bearing Tables	
Machine Tool Applications	
TAC B Series	
Electric Injection Molding Machine Applications	
TAC02 and 03 Series	
Units for Ball Screw Support	P114-115
Features	
Numbering System	
Bearing Tables	

5. Precision Deep Groove Ball Bearings

Precision Deep Groove Ball Bearings	P118-120
Features	
Numbering System	
Bearing Tables	
T1X Type (Polyamide resin cage)	
60, 62 and 63 Series	

6. Peripheral Equipment

Gauges	P124-127
GR Gauges	
Features	
Numbering System	
GTR Gauges	
Features	
Numbering System	
GN Gauges	
Features	
Numbering System	
Bearing Monitor	P128
Bearing Heater	P129
Grease Replenishing System	P130-131
Oil-Air Lubricator	P132-133
Sealed Precision Spacers for Machine Tool Spindles	P134-135

Part5. Technical Guide

1. Life	P138-145
· Rolling Fatigue Life and Basic Load Rating	
· New Life Theory	
2. Static Load Ratings and Static Equivalent Loads	P146-147
3. Angular Contact Ball Bearing Combinations	P148-151
· Features of Each Combination	
· Universal Combination	
4. Preload and Rigidity	P152-169
· Types of Preload and Rigidity	
· Preload and Rigidity Tables	
5. Limiting Speeds	P170-171
6. Lubrication	P172-175
7. Bearing Tolerances	P176-183
· Tolerance for Radial Bearings	
· Tolerances for Tapered Bores	
· Tolerances for Angular Contact Thrust Ball Bearings	
8. Designing of Shafts and Housings	P184-188
· Fitting of Shafts and Housings	
· Shafts and Housing Tolerance	
· Shoulder and Fillet Dimensions	
· Chamfer Dimensions	
9. Spacers	P189-193
· Spacer Dimensions	
· Position of Spray Nozzle	

Part6. Bearing Handling

1. Mounting	P196-209
1. Cleaning the Bearings and Related Parts	
2. Checking Dimensions of Related Parts	
3. Mounting Procedures	
4. Inspection after Mounting	
2. Operational Inspection	P210-211
3. Initial Running-in Procedures	P212-213

Part7. Bearing Failure Diagnosis

1. Bearing Failure and Measure	P216-219
2. Diagnosis with Sound and Vibration	P220-225

Part8. Appendices

Tolerances for Shaft Diameters	P228-229
Tolerances for Housing Bore Diameters	P230-231
Values of Standard Tolerances for IT Grades	P232-233
Hardness Conversion Table	P234
Physical and Mechanical Properties of Material	P235-236
Old and New Number Contrast Table	P237
Method for Measuring Axial Clearance of Combined Angular Contact Ball Bearings	P238
Request for Specification Investigation	P240

Part1. NSK Super Precision Bearings

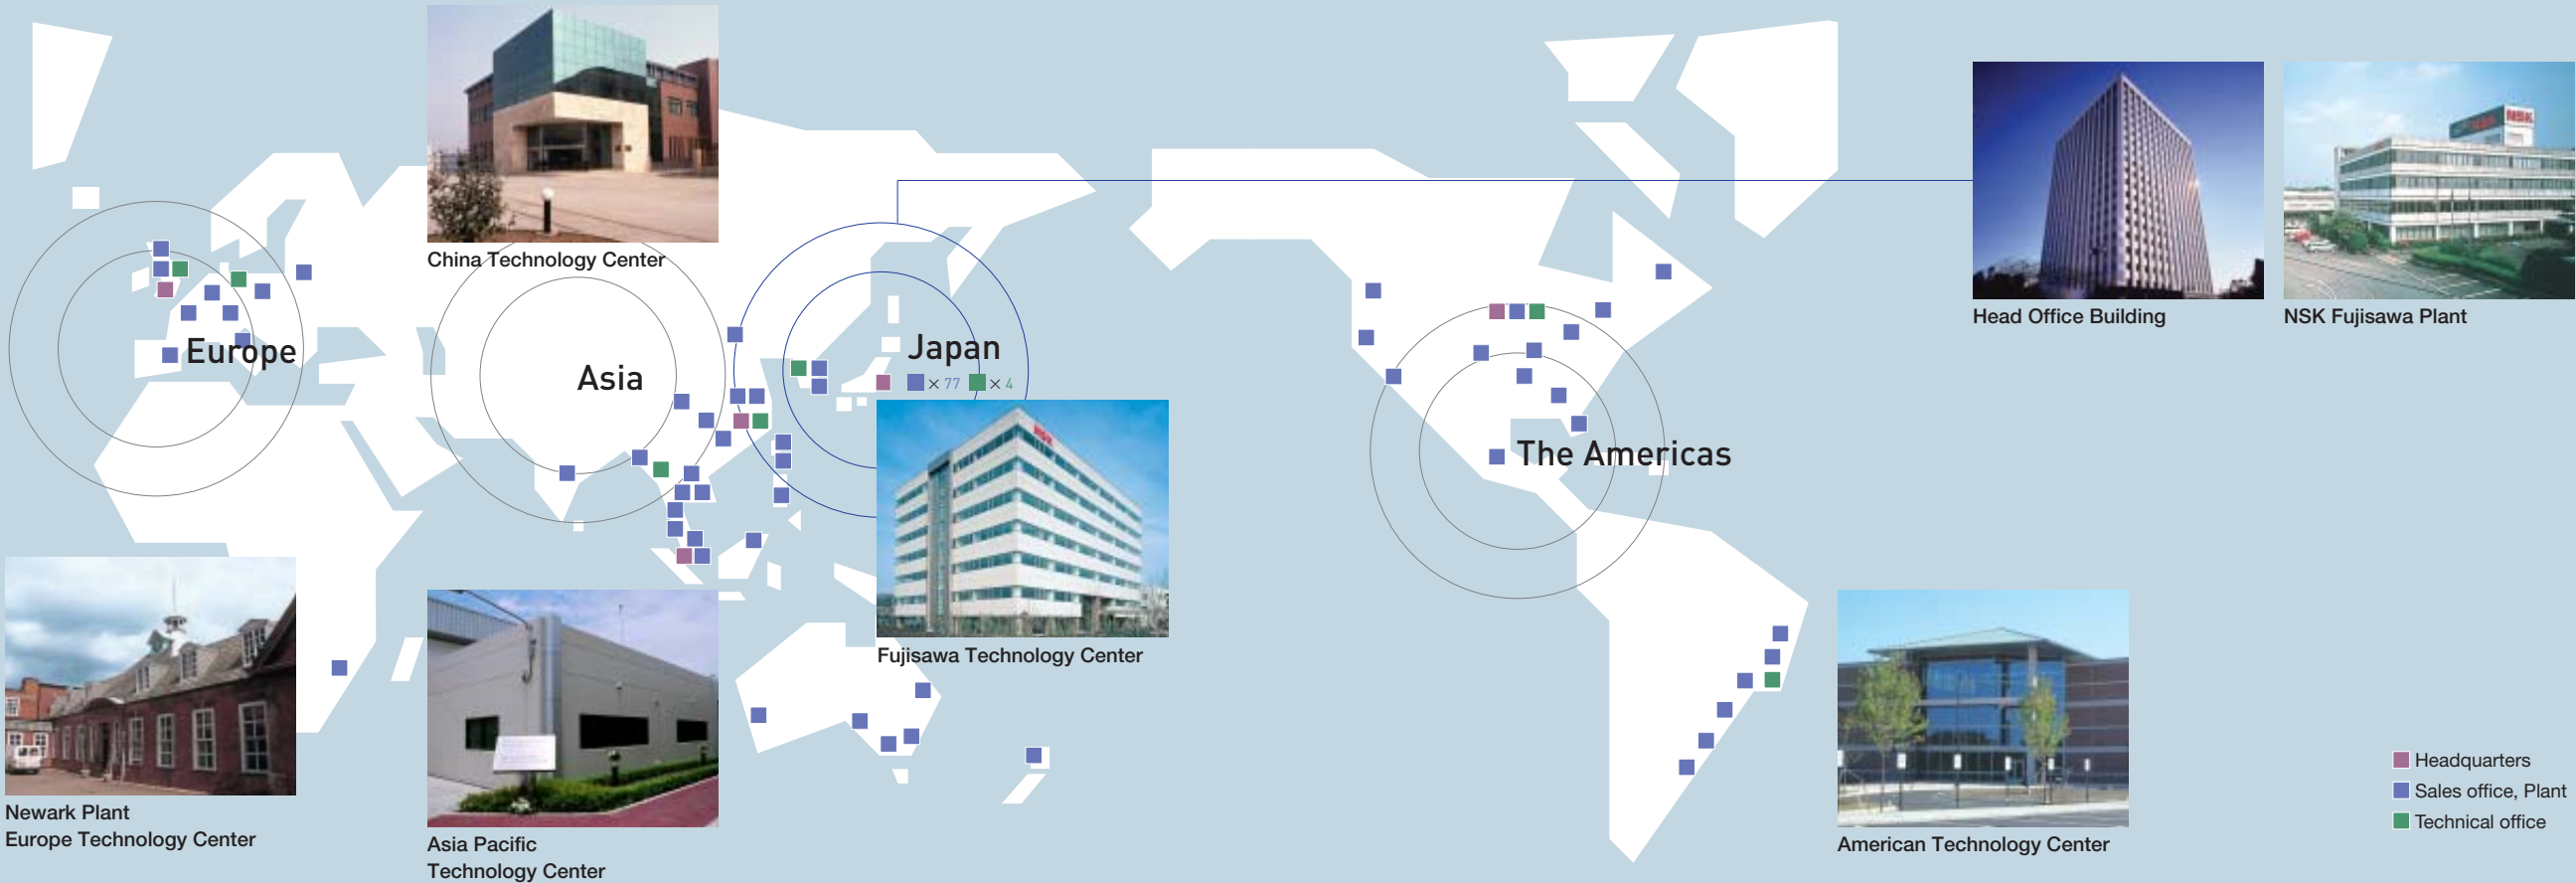

Global Support Capabilities	P6
Development Capabilities	P8
Quality Control and Production Capabilities	P10

## Uniform support system anywhere in the world

NSK is committed to manufacturing and selling products with consistently high quality anywhere in the world under the leadership of Technology Centers in the four major global markets. NSK's sales offices, with expert staff that constantly explore customer needs, promote global network management that encompasses Technology Centers as well as production sites.

NSK can respond quickly and effectively to the various needs of customers and supports their business development efforts in any region.

### Global network management provides optimal, high-quality products

NSK has established a highly-developed information network centered on Technology Centers located in the four major markets of the world—Europe, the United States, Asia and Japan. With this network, we are able to gather information, in real time, related to the changes and trends in any market in the world. As a result, we can react quickly to meet changing customer needs to supply optimal, high-quality products.

Information system directly linked to customers

### Technology Center customer support

Technology Centers in four major markets provide technical support to customers in their respective regions. This support enables our customers to use NSK's products under ideal conditions and achieve the best possible performance.

### Custom products for unique customer applications

Each Technology Center works closely with our customers to determine their precise application needs. In doing so, we assist them in identifying the right NSK product for each application to realize maximum efficiency and cost effectiveness. Upon request, we can also supply completely customized products to satisfy highly-specialized customer needs.

### Our global support network is available wherever our customers are located

Our extensive global network is able to receive orders and supply products anywhere in the world. NSK's distributors cover the globe and maintain an inventory of all critical products in every major market and location, making it possible to supply products to customers without delay. NSK also provides technical support worldwide to help customers determine the best bearing for each application, respond quickly to any questions, and immediately address any problems our customers may encounter.

## NSK's key technology

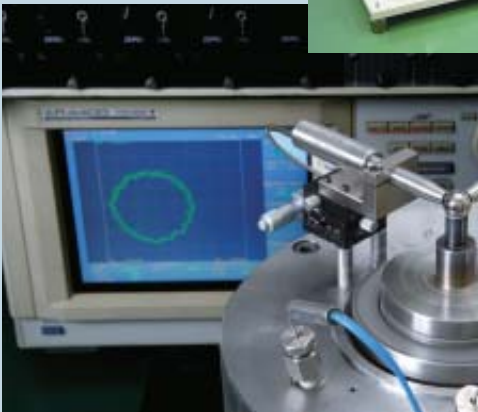

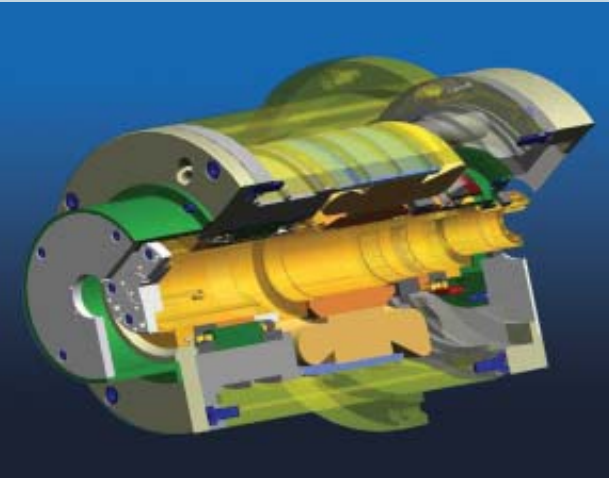

NSK's key technology is Tribology, the science of friction and wear.

Tribology is a technology that focuses on saving energy and conserving resources by reducing friction and wear as well as preventing machine failure and thereby increasing reliability.

With tribology positioned at its core, NSK will further expand its four key technologies: analysis technology for thoroughly eliminating energy losses; evaluation technology for ensuring exacting responsiveness to market needs; lubrication technology for reducing energy losses and enhancing functionality; and material technology for extending product life, and will forge ahead in the development of environmentally friendly products based on the foundation of these technologies.

### Analysis Technology

NSK developed its own software, BRAIN (Bearing Analysis In NSK), which enables digital simulations of friction-related movement and performance by applying Tribology. The combined use of this simulation data with an effective factor method (EFM) realizes advanced computer-aided engineering (CAE).

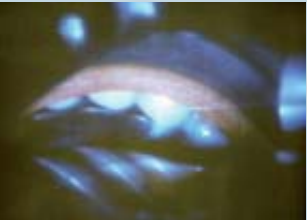

### Evaluation Technology

NSK has established an evaluation technology that spans a wide range of applications by employing advanced technologies such as nano-order runout measurement using ultra high-precision measuring instruments. Our evaluation technology contributes to the development of cutting-edge products that correspond with increasingly sophisticated market needs.

### Lubrication Technology

Through the relentless application of Tribology, NSK's key technology, NSK has pursued lubrication technologies that allow machines to deliver maximum performance and NSK's accomplishments in these efforts contribute to saving energy and resources, thereby conserving the global environment.

### Material Technology

Research and development across a wide range of material technologies has been conducted to produce ever-higher performing products. Products made of NSK's proprietary materials deliver long life under harsh conditions, are maintenance-free, and also support all industries.

## The highest level of quality in the world

NSK precision bearings deliver the highest level of accuracy, supported by our production capability, state-of-the-art equipment and extensive manufacturing expertise, as well as our commitment to applying the same rigorous quality control procedures at each stage of the production process in every NSK facility.

NSK focuses its efforts at its global production sites in Japan and England on offering products with high accuracy to quickly meet the diverse needs of customers worldwide.

6 Packaging

**Manufacturing technologies to produce high accuracy products**

To maintain our reputation for manufacturing precision bearings with the highest degree of accuracy in the world, all precision bearings are checked to nanometer accuracy.

**Global production in England and Japan**

NSK's precision bearings are made in both England and Japan. The combined expertise and locations of these manufacturing facilities allow us to meet every customer need.

NSK Newark Plant

NSK Fujisawa Plant

**NSK symbol**

NSK's golden box guarantees the highest level of accuracy.

**Complete quality control and environmental responsibility**

As members of an ISO 9001-certified enterprise, all NSK plants adhere to strict international standards for quality control. NSK is also making an all-out, companywide effort to address environmental concerns as a top priority.

ISO 9001 Certification

ISO 14001 Certification

# High Performance in the Next Generation

NSK continually challenges the status quo to explore new possibilities. As our design philosophy does not allow us to compromise quality in manufacturing, we are driven to develop total solution technologies.

By using the latest material and analysis technologies we are able to design and manufacture exceptional, high performance precision bearings.

NSK will always strive to achieve the quality and performance that will be required in next generation bearings.

Part2. Features of Precision Bearings

Metallurgical Technologies to Extend Bearing Life	P14
Ceramic Rolling Elements	P16
Cages	P18
Bearing Components	P20
Product Range	P22
Performance of Each Bearing Type	P24

Three types of steel materials support the long life and high performance of NSK super-precision bearings

NSK has established groundbreaking evaluation techniques for inclusions in steel and steel-making procedures. These technologies make it possible to develop materials for long-life, high-performance rolling bearings.

Three types of steel materials—SHX steel that withstands ultra high-speed rotation environments, EP steel that exhibits high reliability under heavy load environments, and Z steel that achieves extended operation life under general conditions—support NSK super-precision bearings.

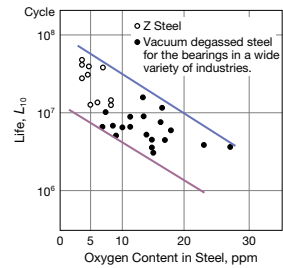

Z Steel as a Standard Material for Super-Precision Bearings

**Z Steel** Standard Long Life Material  
1.8 Times Longer Fatigue Life than Conventional Vacuum Degassed Steel

It is well known that the rolling fatigue life of high carbon chrome bearing steel (SAE52100, SUJ2) used for rolling bearings is significantly affected by non-metallic inclusions. Life tests show that oxide non-metallic inclusions exert a particularly adverse affect on rolling fatigue life. Z Steel, with lower oxide non-metallic inclusions, exhibits improved performance.

**Features of Z Steel**  
Z Steel is produced by reducing non-metallic inclusions, oxides and other inclusions such as Ti, or S, inside the steel. Bearings made of this steel deliver significantly extended service life, up to 1.8 times longer, compared to conventional vacuum degassed steel.

Oxygen Content in Steel and Operating Life

Products made of Z Steel

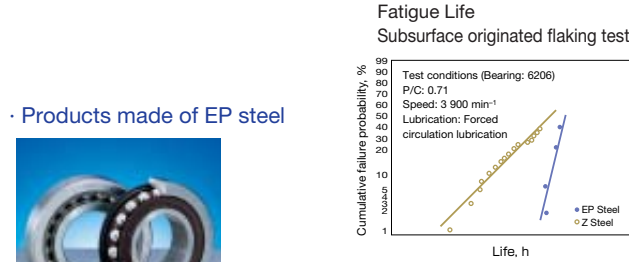

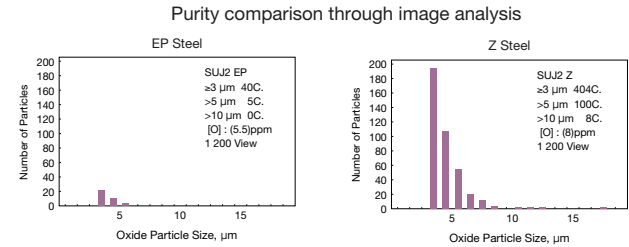

NSK uses Z Steel as a standard material

EP Steel for Higher Reliability under Heavy Load Environments

**EP Steel** Extra Long Life and High Reliability  
3 Times Longer Fatigue Life than SUJ2 Steel

Development of innovative techniques for evaluating oxide non-metallic inclusions and the establishment of steel-making procedures resulted in EP steel that achieved a dramatic advance in bearing reliability.

- Features of EP Steel**  
Bearings made from EP Steel exhibit increased reliability due to minimal variation in life resulting from the new evaluation technique and significantly reduced impurities.
- The establishment of a new evaluation technique**  
NSK established the NSK-ISD2 Method, an image analysis system and a special steel-making procedure, to improve the evaluation of oxide non-metallic inclusions.
- Improvement of steel-making procedures**  
The introduction of this technique into steel manufacturing technology significantly improved purity and reduced non-metallic inclusions compared to Z Steel. EP Steel contains fewer large particles than either Vacuum Arc Remelted (VAR) or conventionally refined Z Steel.

Products made of EP steel

Ball Screw Support Bearings

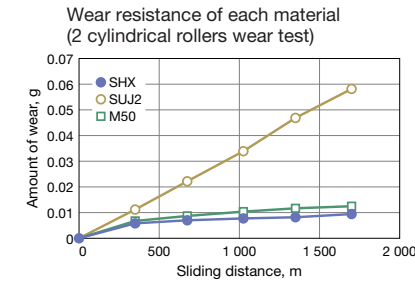

SHX Steel Endures Ultra Speed Rotation Environments

**SHX Steel** Heat Resistant Steel Extends the Life of Bearings Used in Ultra High-Speed Applications  
4 Times Longer Fatigue Life than SUJ2 Steel, at 20% Higher Speed

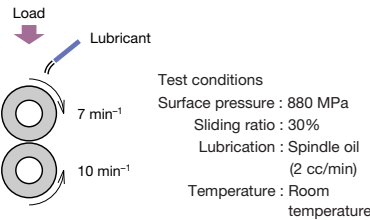

SHX is a heat-resistant steel resulting from NSK's special heat treatment technology.

- Features of SHX Steel**  
SHX steel exhibits similar heat resistant performance to M50 steel, which is used for bearings on the main shaft of jet engine applications where temperatures reach 300°C, and features lower friction performance, while at the same time exceeding M50 steel in wear and seizure resistance and fatigue life. This level of heat resistance, lower friction performance and indentation resistance represent ideally suited steel characteristics for ultra high-speed machine tool bearings. Products made of SHX Steel

Ultra High-Speed ROBUST Series for Ultra High-Speed Machine Tool Main Spindles

Less heat is generated, making possible ultra high-speed rotation.

Ceramic hybrid bearings have many excellent performance characteristics such as heat resistance, extended life, light weight, lower thermal expansion, electrically non-conductive, and thus can be used in an infinite number of applications as a new generation material. Early on NSK's knowledge of materials and bearing manufacturing led us to utilize one ceramic in particular, silicon nitride ( $\text{Si}_3\text{N}_4$ ), for the rolling elements in ceramic hybrid bearings. Hybrid bearings with ceramic elements have earned a good reputation in the field for ultra high speed combined with ultra high accuracy, a performance combination that is not achievable in bearings with steel rolling elements.

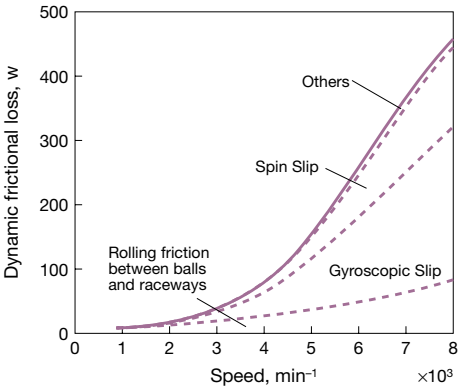

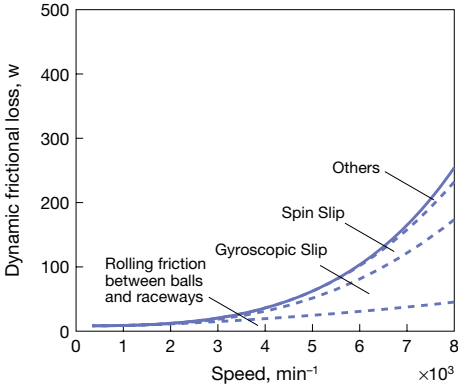

High speed and low-heat generation

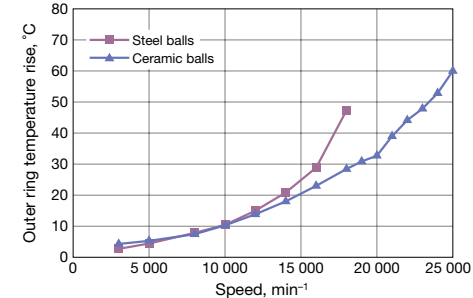

- **Light weight**  
As the density is 40% lower than that of steel, the centrifugal force applied to the rolling elements is smaller, thus extending bearing life.
- **Low coefficient of linear expansion**  
In applications involving high speed operation, although the temperature of the bearing is high, this low coefficient results in lower preload and lower heat generation.
- **Low friction**  
The slip of the rolling element during operation is reduced, and this means less heat is generated.

Less heat is generated, making possible ultra high-speed rotation.

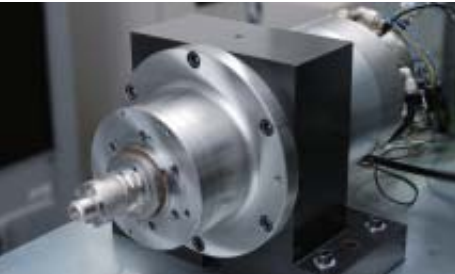

Calculated result of heat generation

The Outer Ring Temperature Rise in High Speed Operation

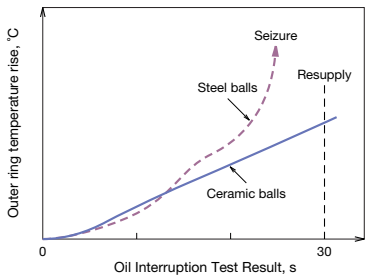

NSK Spindle that achieved 4 million  $d_m n$  using ceramic ball bearings

Seizure Resistance

Relative to steel balls, ceramic balls have a higher seizure resistance.

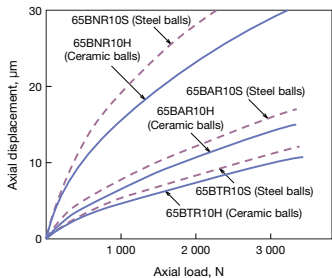

Cutting by NSK Spindle using Ceramic Ball Bearing

End Mill:  $\phi 16$   
Work Material: A5052  
Rotational speed: 20 000 min<sup>-1</sup>  
2 500 cm<sup>3</sup>/min

High Rigidity

Ceramic balls have a Young's Modulus that is 50% higher than that of steel, making it an ideal material for use in machine tool spindles requiring rigid cutting performance.

Cutting by NSK Spindle using Ceramic Ball Bearing

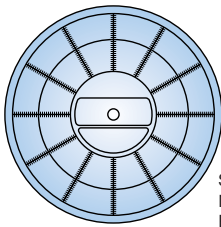

Face Mill:  $\phi 80$   
Work Material: S50C  
Rotational speed: 1 200 min<sup>-1</sup>  
504 cm<sup>3</sup>/min

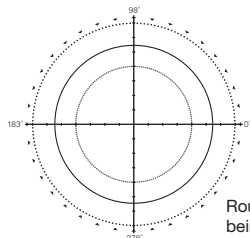

High Accuracy

NSK's expertise in the manufacturing of balls and rollers over the years along with improvements in the sintering process and the grade of materials used enables NSK to produce ceramic balls and cylindrical rollers that feature a higher level of accuracy

than steel materials. Bearings using these high-accuracy ceramic rolling elements support high-accuracy machining.

Ceramic ball bearing

Ceramic roller bearing

Engineered polymer cages with higher speed capability and lower friction

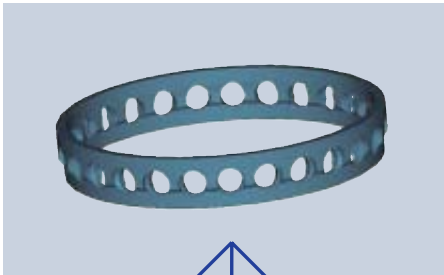

Because of light weight (polymer density is 1/6 that of brass), easy formability, and high corrosion resistance, polymer materials are used widely in bearing cages. Polymers can be engineered to have lower friction and thus lower heat generation and higher speed capability. Polymers can be engineered for low wear, thus extending grease life. The engineered polymer cage is well suited for bearings used in machine tool main spindles.

Cage for Angular Contact Ball Bearings

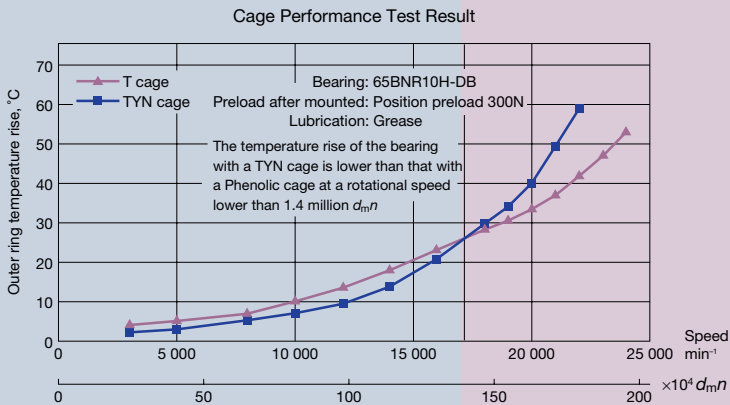

Ball Guided Polyamide Cage (TYN)

Low Noise

- This special design allows the bearing to have lower friction and lower noise.
- This cage is effective with grease lubrication. The internal free space of the bearing in this cage is larger than that with outer ring guided cage so, it is possible to keep more grease inside of the bearing.
- The period of the grease running-in procedure for a bearing with this cage is shorter than that of a bearing, with a phenolic cage.

Ultra High-Speed Angular Contact Ball Bearings ROBUST Series

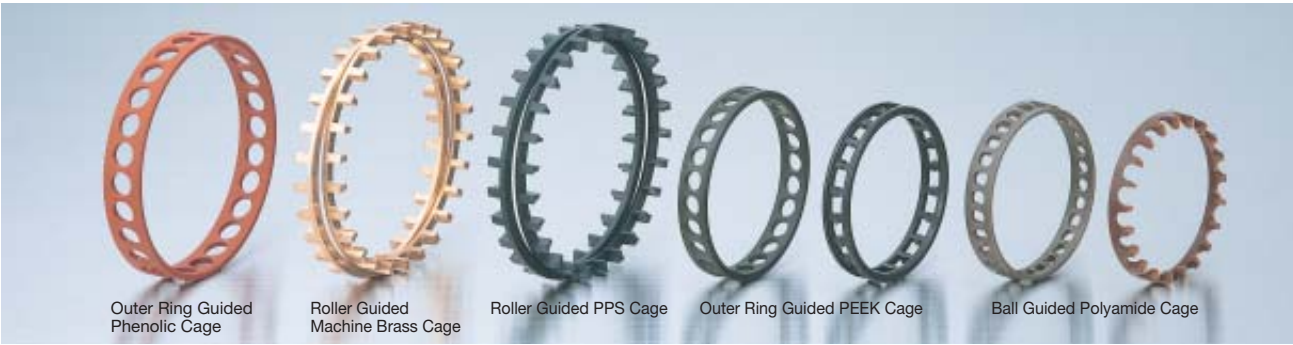

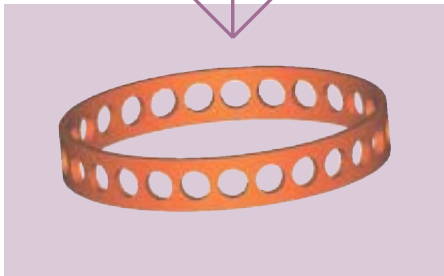

Outer Ring Guided Phenolic Cage (T, TR)

Ultra High-Speed

The rotational movement of the outer ring guided cage is more stable in high-speed operation.

Standard Series Angular Contact Ball Bearings  
Standard Series  
Ultra High-Speed Angular Contact Ball Bearings ROBUST Series

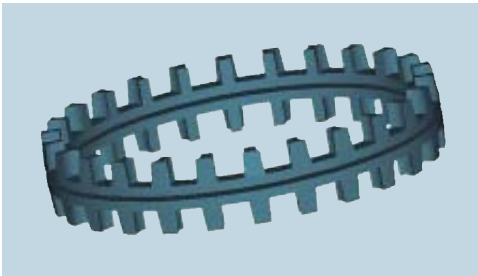

Cage for Double-Row Cylindrical Roller Bearings

Roller Guided PPS Cage (TB) Engineered Polymer

High Rigidity

- Optimal roller-guided cage design with consideration for strength and friction.
- Excellent physical properties include higher strength, toughness, wear and fatigue resistance compared to current polyamide cage material.
- High temperature resistance up to a maximum of 220°C.

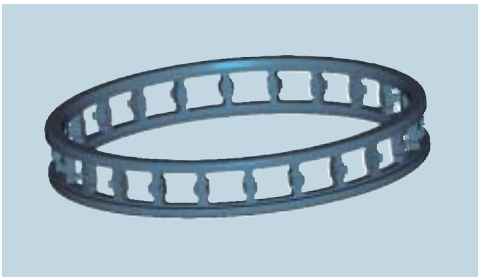

Double row CRB High Rigidity Series

Cage for Single-Row Cylindrical Roller Bearings

Outer Ring Guided PEEK Cage (TP) Engineered Polymer

Ultra High-Speed

- Minimizing cage deformation to permit stable high-speed rotation.
- High temperature resistance up to a maximum of 240°C.
- Excellent wear-resistant performance and suited to minimal oil lubrication.
- Physical properties include high strength, toughness, wear and fatigue resistance.

Ultra High-Speed Single Row CRB Robust Series

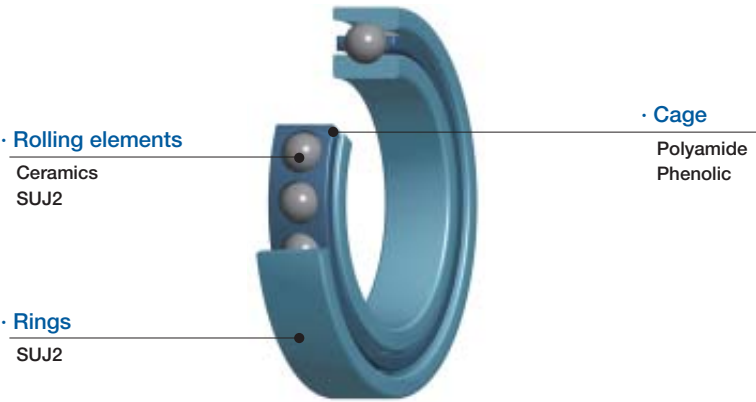

Roller Guided Machined Brass Cage (MB, MR)

General Purpose

- This cage demonstrates high temperature resistance, high strength, and high rigidity.

Several types of super precision bearings are available from NSK, including the ROBUST™ series of high performance bearings, the special series of bearings for unique and specialized applications, and the standard series bearings.

**High Precision Angular Contact Ball Bearings**

Standard Series

Basic NSK super precision bearings manufactured to conform to ISO standard.

- 70xx, 72xx, 79xx series
- Three types of contact angle: 15° (C), 25° (A5), 30° (A)
- Two types of cage design: Select either phenolic (TR) or polyamide (TYN), depending on application requirements

**Ultra High-Speed Angular Contact Ball Bearings**

ROBUST Series

**ROBUST Series (BNR, BER)**

High performance bearings developed for high-speed operation with low temperature rise. Suitable for ultra high precision machining applications, and ultra high-speed applications.

- Two types of contact angle: 18° (BNR), 25° (BER)
- Two types of ball material: steel (S type) and Ceramic (H and X type)
- Two types of cage design: Select either phenolic (T) or polyamide (TYN), depending on application requirements
- ROBUST series also can be used for ultra high-speed applications of over 3 million  $d_m n$

**Sealed Angular Contact Ball Bearings**

Special Series

Pregreased and sealed to reduce handling problems. Suitable for maintenance of machine tool spindles.

- Standard series super precision angular contact ball bearings
- ROBUST series high-speed angular contact ball bearings
- Bore size range:  $\phi$ 30–100 mm in ISO series 10 and 19 (70xx and 79xx)

**High-Speed Angular Contact Thrust Ball Bearings**

ROBUST Series

**ROBUST Series (BAR, BTR)**

High rigidity thrust bearings for lathe applications.

- Two types of contact angle: 30° (BAR), 40° (BTR)
- Two types of ball material: steel (S type) and Ceramic (H type)

**Ultra High Precision Angular Contact Ball Bearings**

ROBUST Series

**ROBUST Series (BGR)**

High Performance bearings developed specifically for internal grinding or high-speed motor applications under spring preload.

- Bore size range:  $\phi$ 6–25 mm, contact angle: 15°
- Two types of ball material: steel (S type) and Ceramic (H and X type)
- Non separable type
- Universal combinations (DU and SU)

ROBUST series is the high performance series of NSK super precision bearings.

**Ultra High-Speed Single Row Cylindrical Roller Bearings**

ROBUST Series   Standard Series

High performance cylindrical bearings designed for ultra high-speed applications, such as machining center spindles.

- Two types of cage material: Brass (MR)<sup>(1)</sup> and PEEK resin (TP)
- Three types of roller material: Steel, SHX and Ceramic
- Ultra high-speed ROBUST RXH design can be used up to 2.2 million  $d_m n$

<sup>(1)</sup> MR cage is used in the standard series

**Double Row Cylindrical Roller Bearings**

Standard Series

**High Rigidity Series**

Designed to deliver high rigidity in high-speed applications such as lathe spindles.

- Two types of cage material: Brass (MB), PPS resin (TB)
- Standard specification E44: Outer ring oil holes and groove

**Angular Contact Thrust Ball Bearings for Ball Screw Support**

Special Series

**for Machine Tool Applications**

High rigidity thrust bearings designed specifically for ball screw support applications in machine tools.

- Contact angle: 60°
- Can be universally matched to any required rigidity specification or life cycle
- A pregreased line using special grease is also available
- A new series is available, supplied with contact seals and waterproof grease

**Angular Contact Thrust Ball Bearings for Ball Screw Support**

Special Series

**for Injection Molding Machines**

The high load capacity design delivers five times the life expectancy compared to ball screw support bearings for machine tool applications of a similar size. The number of rows can also be reduced.

- Easier handling than tapered roller bearings or thrust spherical roller bearings as a result of non separable configuration
- Optimum ball bearing design results in lower rotational torque
- Can be universally matched to any required rigidity specification or life cycle

**High Precision Deep-Groove Ball Bearings**

Special Series

**Special Series**

Suitable for high-speed and high precision motors.

- Two types of cage: Ball guided polyamide cage (T1X,TYA)
- For quiet operation, with low vibration

Designed to achieve high-speed operation combined with low heat generation—ROBUST Series

Benefits

1 Low Heat Generation

2 High Seizure Resistance

3 Better Temperature Stability “Robustness”

4 Stable during High-Speed Operation

High performance

**Spinshot™ II XE Type**  
Suitable for silent operation due to reduced air-noise achieved through oil-air lubrication design

- Material of Inner/Outer Rings: Heat Resistant Steel “SHX”
- Ceramic Balls
- Cage selection based on speed requirements
- Outer Ring Guided Phenolic Cage: up to 2.5 million  $d_m n$
- Outer Ring Guided PEEK Cage: over 2.5 million  $d_m n$

**ROBUST Series X Type**  
High performance bearings demonstrating high wear and seizure resistance during ultra high-speed operation

- Material of Inner/Outer Rings: Heat Resistant Steel “SHX”
- Ceramic Balls
- Outer Ring Guided Phenolic Cage

**ROBUST Series H Type**  
High performance bearings that combine high-speed operation with low heat generation

- Material of Inner/Outer Rings: Steel
- Ceramic Balls
- Cage selection based on speed requirements
- Ball Guided Polyamide Cage: up to 1.4 million  $d_m n$
- Outer Ring Guided Phenolic Cage: over 1.4 million  $d_m n$

**ROBUST Series S Type**  
Steel ball bearings for optimal cost

- Material of Inner/Outer Rings: Steel
- Steel Balls
- Ball Guided Polyamide Cage

High speed

Features of “XE” series

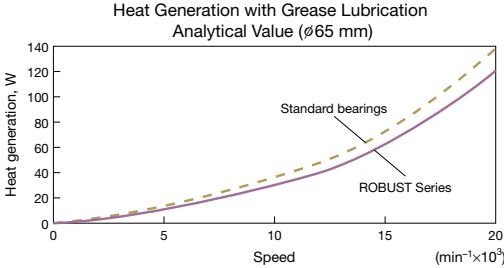

- High-Speed Performance (in Position Preload)**  
High-speed performance in position preload to a maximum of 2.5 million  $d_m n$  with jacket cooling (Max. 2.7 million  $d_m n$  without jacket cooling).
- Silent Operation**  
Silent operation 3-5 dB quieter than conventional oil-air lubrication.
- Orientation**  
Remains stable in either vertical or horizontal spindle orientation.
- Reduced Air Consumption**  
Air consumption can be 1/3 relative to conventional oil-air lubrication.

Analysis Data

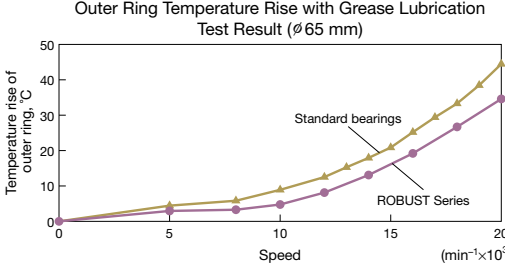

Sophisticated analysis software takes into account the slip inside the bearing and simulates temperature rise to establish optimum design specifications. By reducing the heat generated, ROBUST series bearings remain much more stable during high-speed operation than current series bearings.

High performance bearings that combine high-speed capability with high rigidity—ROBUST Series

Benefits

1 High-Speed Capability

2 Low Heat Generation

3 High Accuracy

**High-Speed Angular Contact Thrust Ball Bearings**  
**BTR10 Series**  
40° contact angle and high axial rigidity and low heat generation. Interchangeable with TAC series.

**High-Speed Angular Contact Thrust Ball Bearings**  
**BAR10 Series**  
30° contact angle delivers higher speed capability. Interchangeable with BTR and TAC series.

**Double Row Angular Contact Thrust Ball Bearings**  
**TAC Series**  
60° contact angle with the highest axial rigidity.

Ultra high-speed internal grinding spindle bearings for high accuracy and longer life—ROBUST Series (BGR)

Benefits

1 Optimum Internal Design

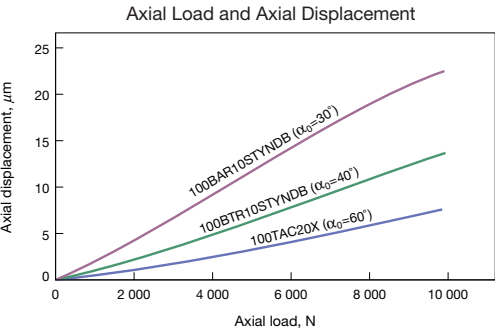

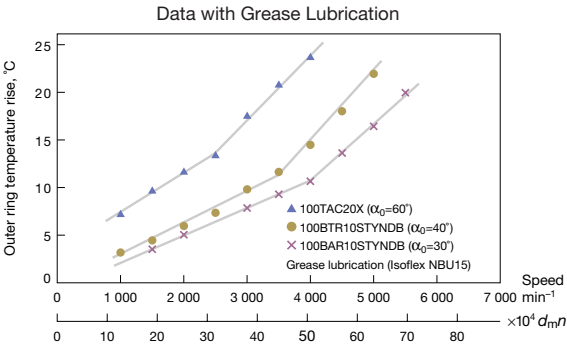

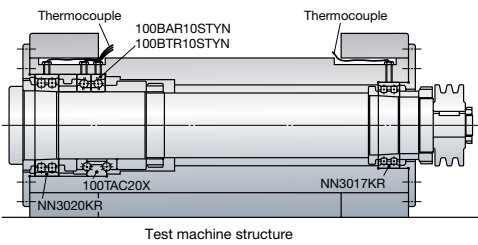

2 Easy Handling Due to Non Separable Feature

3 Free Choice of Arrangement with Universal Combination

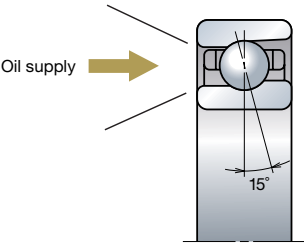

Features of Angular Contact Thrust Ball Bearings

- High Accuracy**  
 Due to the high degree of accuracy, they are particularly suited for lathe spindle applications.
- Interchangeable**  
 To adjust spindle stiffness characteristics, BTR and BAR series can be interchanged with TAC series, with minimal modification of the spindle. (See figure on the right).

Features of the BGR Series

- Optimum Design**  
 Optimum outer ring guided cage design for better lubrication.  
 Inner ring shoulder relieved to enable a stable supply of oil into the bearing.
- Longer Life**  
 Heat resistant SHX steel for longer life.
- Easy Handling**  
 Non separable structure makes handling easy.
- Ultra High Accuracy**  
 ISO class 2 (ABMA ABEC9) is the standard.
- Universal Combination**  
 Bearings can be configured in the usual arrangements of DB/DF/DT, as well as a variety of other arrangements.

(for Machine Tool Applications)

High performance special bearings with high rigidity—TAC B Series

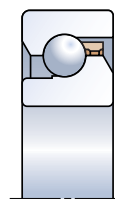

## Benefits

- 1 Longer Life
- 2 Lower Torque
- 3 Easy Handling
- 4 High Accuracy

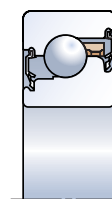

### Features of Ball Screw Support Bearings for Machine Tools

- **Longer Life**  
Components made from longer life EP extremely purified steel.
- **High Rigidity**  
Special internal design (60° contact angle and more balls) for higher axial rigidity.
- **Lower Torque**  
Lower starting torque than either tapered or cylindrical roller bearings means high rotation accuracy even at low driven power.
- **Universal Combination**  
Bearings can be configured in the usual arrangements of DB/DF/DT, as well as a variety of other arrangements.  
A pregreased option is also available (with Alvania No.2 grease).
- **Easy Handling and Increased Reliability**  
New series with contact seals and waterproof grease has higher reliability and easier handling.  
Single universal combination (SU) is the standard for this series.
- **High Running Accuracy**  
New polyamide cage for high running accuracy.

Cross Section of TAC B

With Seal Cross Section of TAC B

(for Injection Molding Machines)

These special high performance bearings can simplify machine design and reduce costs—TAC 02, 03 Series

## Benefits

- 1 Space Saving, High Load Capacity
- 2 High Reliability
- 3 Easy Handling
- 4 Reduced Torque from Optimized Design

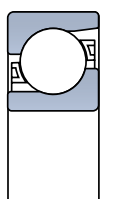

### Features of Ball Screw Support Bearings for Injection Molding Machines

- **High Reliability**  
High load capacity design delivers five times the life value compared to the similarly sized TAC B series.
- **Easy Handling**  
Easier to handle and use than tapered roller bearings or thrust spherical roller bearings due to the non separable design.
- **Simplified Design Leads to Reduced Costs**  
Preload is preset so assembly is fast and without any preload adjustment. Design of special parts for preload adjustment is unnecessary, which saves time and cost.
- **Lower Rotational Torque**  
Optimal internal design for lower torque (i.e., in cases where roller bearings are currently being used because of large load, these bearings can be used to reduce the bearing torque generated by roller bearings).

Cross Section of the Bearing for Machine Tools and Injection Molding Machines

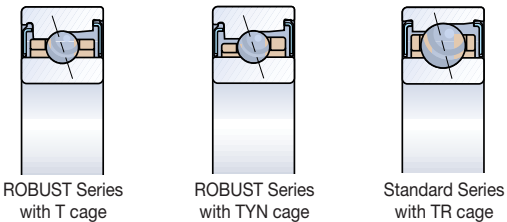

Cross Section of TAC03AT85

Suitable for spindle maintenance—ROBUST Series and Standard Series

Features of Sealed Angular Contact Ball Bearings

- Easy Handling**  
 No need to grease the bearing during spindle assembly.
- Environmentally Friendly**  
 Sealed design avoids grease loss.

Sealed Precision Spacers

Sealed spacers eliminate the possibility of contamination  
Precision spacers available for machine tool spindles

Features of Sealed Precision Spacers

- Environmentally Friendly**  
 Sealed design prevents grease loss.
- High Reliability**  
 Reduced contamination from dust or coolant in grease lubricated spindles.

MTS, MTE, ENS

Features of Greases for Machine Tool Spindles

- MTS** Contains urea thickener and delivers higher heat resistance. Recommended for use with ultra high speed machine tool spindles
- MTE** Formulated to handle higher load capacities. Recommended for use in high speed machine tool spindles.
- ENS** Environmentally friendly thanks to biodegradability.

MTE and MTS are available in 100 g tubes as well as 1 kg cans.

# Selecting the Right Bearing is Critical

Precision bearings are designed to deliver the high accuracy, high rotational speed, and high rigidity needed for demanding machine tool applications. As each application has its own unique requirements, and each type of bearing has different characteristics, it is essential to select the type of bearing based on the specific demands of a given application.

## Take Advantage of NSK Technical Support when Selecting Bearings

NSK is committed to helping customers select the proper bearings that will deliver the best performance based on the application involved.

When designing a new spindle, including ultra high speed, specialized or custom applications, or making your bearing selection, please don't hesitate to ask us for technical assistance. We have the experience and expertise in state-of-the-art, high speed, main shaft spindle technology to assure that you get the very best bearings for your application.

For more information on the latest NSK technology, please visit our Web site or call today.

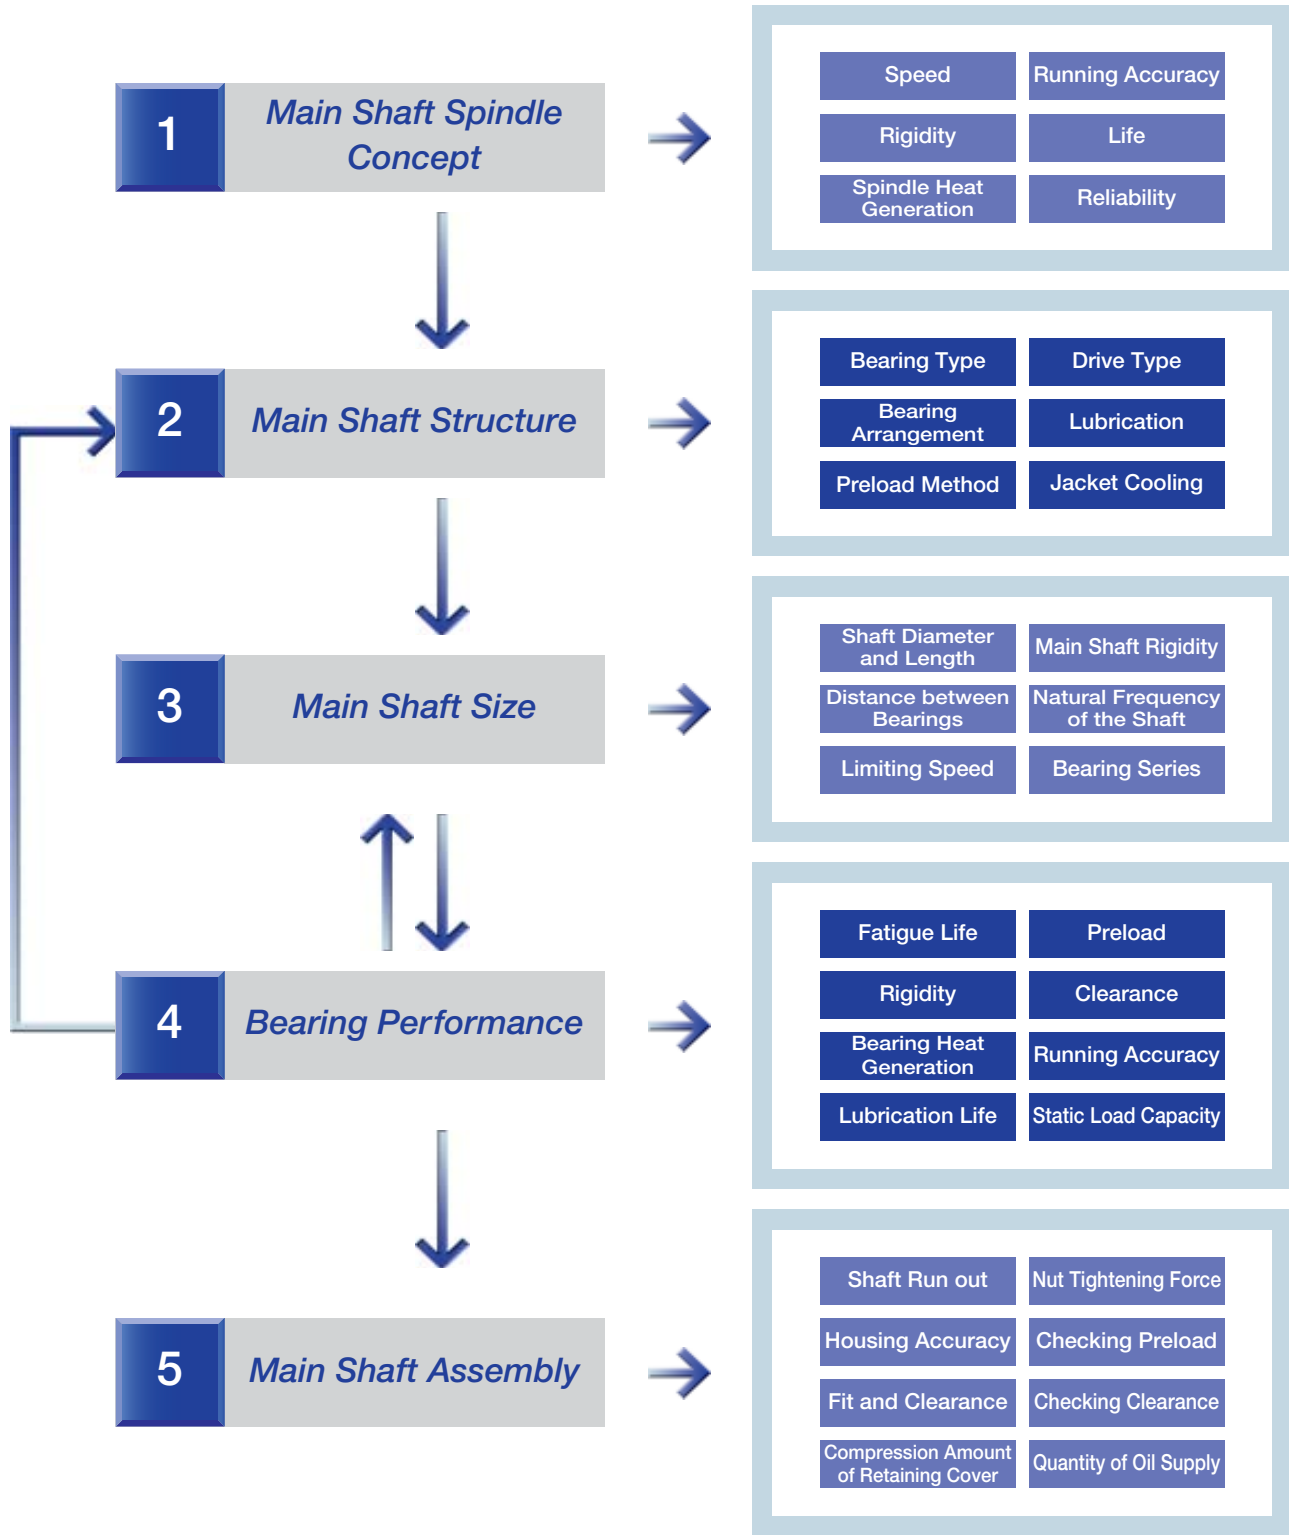

NSK Web Site

Part3.	Bearing Selection	P36
	Typical High-Speed Main Shaft Spindle Structures	P38
	Other Spindle Structures	P40
	Features of Angular Contact Ball Bearings	P42
	Features of Cylindrical Roller Bearings	P44

The chart below outlines the correct five step procedure to follow when selecting the proper bearing for a typical high-speed spindle application, including the factors to be considered in each stage of the selection process.

Remember, NSK technical support is always at your disposal when designing a new spindle, an ultra high-speed spindle or a spindle for a unique specialized application. We offer customers our experience and our expertise in advanced technology.

When designing a new main shaft spindle, we recommend a thorough analysis of the desired spindle performance before selecting the bearing. In designing the spindle, it is necessary to determine which performance factor is most important. For example, deciding if the rotational speed is more important than the rigidity, or vice versa. Once the performance factors are prioritized proceed to the next step.

After the performance analysis of the main shaft has been completed, the next step is to determine the structure of the main shaft. To determine the optimum structure, consideration must be given to each individual component: the bearing design (ball bearing or roller bearing); combination (the number of rows); type of drive (belt, gear, coupling or integral motor); and lubrication system (grease, oil-air, oil mist, or jet). Care must be taken to ensure that the structure is compatible with the criteria and priority established in your analysis of spindle performance. Please refer to the chart on Pages 38–39, which shows the relationship between the main shaft structure and its rigidity and speed.

**Part 3**

After the structure has been determined, the dimensions of the shaft must be determined, including diameter, length, and distance between the bearings. The size of the main shaft will determine the limiting speed of the bearing, the rigidity of the main shaft, and the natural frequency of the main shaft. As the size, type, combination of bearing used, and the method of lubrication all affect the limiting speed, please refer to Part 4 and Part 5 before making a final determination.

**Part 4**  
**Part 5**

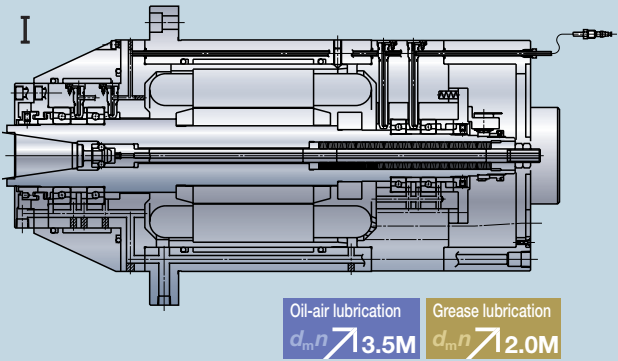

Once the size and type of the bearing are selected, the specification of the bearing should be determined. In order to select the appropriate clearance, or preload, of the bearing it is necessary to consider such factors as fatigue life, axial and radial rigidity, and heat generation. Clearance or preload must be selected carefully, as these factors have the largest impact on overall spindle performance, especially during high speed operation. If the preload is wrong it may cause problems such as early failure or seizure. Sometimes it is necessary to repeat step 3, or even steps 2 and 3, before the most accurate spindle design is achieved.

**Part 5**

After the specification of the main shaft is complete, the final stage is the specification of the assembly method. Accuracy of the shaft and housing at the bearing seats is important. Specify the fit and clearance of the bearings to the shaft and housing. Use the correct nut tightening force to fix the bearings. And double check that the preload, or clearance, after the bearing has been mounted is correct.

**Part 6**

Rotational Speed ( $d_m n$ )

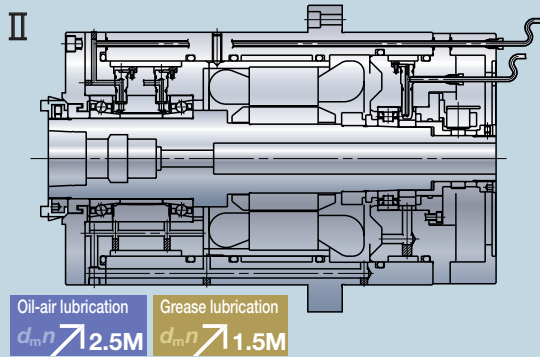

**Bearing Arrangement I**

Front side: Ultra high-speed angular contact ball bearing duplex sets (DT)  
Rear side: Ultra high-speed angular contact ball bearing duplex sets (DT)

Spindles with this arrangement are suited for ultra high speed operation and use constant pressure preload. Although this spindle has lower rigidity it delivers higher speed capability with a lower temperature rise performance relative to a spindle with position preload.

Applications: Machining Center, Grinding Machine, High Frequency Spindle, etc.

Oil-air lubrication  $d_m n \nearrow 3.5M$  Grease lubrication  $d_m n \nearrow 2.0M$

**Bearing Arrangement II**

Front side: Ultra high-speed angular contact ball bearing duplex sets (DB)  
Rear side: Ultra high-speed single row cylindrical roller bearing (In case of angular contact ball bearings, either position or constant pressure preload is applicable)

Spindles with this arrangement are suited for ultra high-speed operation and use position preload. They achieve higher radial and axial rigidity than spindles with Bearing Arrangement I. It is possible to use a cylindrical roller bearing on the rear side, for better slide performance.

Applications: Machining Center, Grinding Machine, High Frequency Spindle, etc.

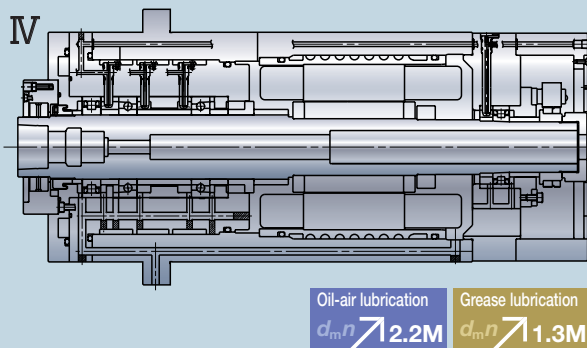

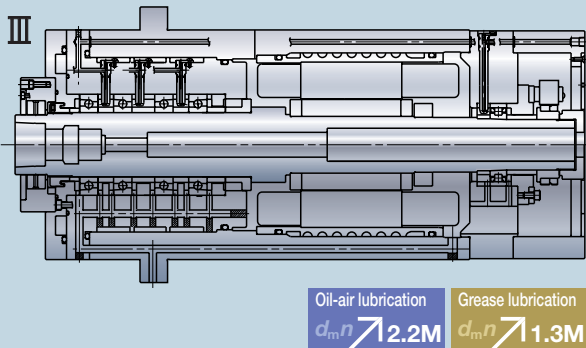

Oil-air lubrication  $d_m n \nearrow 2.5M$  Grease lubrication  $d_m n \nearrow 1.5M$

**Bearing Arrangement III**

Front side: Ultra high-speed angular contact ball bearing quad sets (DBB)  
Rear side: Ultra high-speed single row cylindrical roller bearing (In case of angular contact ball bearings, either position or constant pressure preload is applicable)

Spindles with this arrangement will have lower speed capability, and higher radial and axial rigidity relative to Bearing Arrangement II.

Applications: NC Lathe, NC Milling Machine, Machining Center, etc.

**Bearing Arrangement IV**

Front side: Ultra high-speed single row cylindrical roller bearing, angular contact ball bearing duplex sets (DB)  
Rear side: Ultra high-speed single row cylindrical roller bearing (In case of angular contact ball bearing, either position or constant pressure preload is applicable)

Spindles with this arrangement have high-speed capability similar to spindles with Bearing Arrangement III. As there is a cylindrical roller bearing in the front side, the radial rigidity is high, so it is possible to have both high speed and heavy cuts.

Applications: NC Lathe, NC Milling Machine, Machining Center, etc.

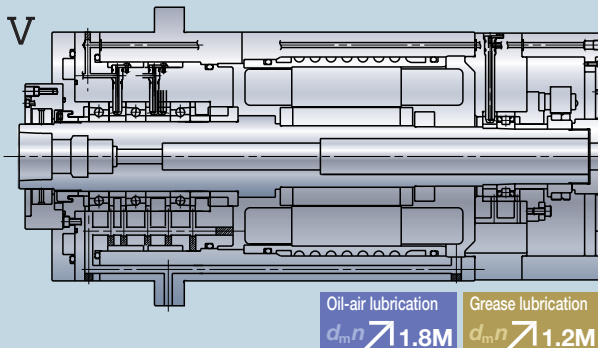

Oil-air lubrication  $d_m n \nearrow 2.2M$  Grease lubrication  $d_m n \nearrow 1.3M$

**Bearing Arrangement V**

Front side: Ultra high-speed angular contact ball bearing triplex sets (DBD)  
Rear side: Ultra high-speed single row cylindrical roller bearing (In case of angular contact ball bearing, either position or constant pressure preload is applicable)

Spindles with this arrangement will have lower speed capability, and higher radial and axial rigidity relative to Bearing Arrangement II, and lower speed capability and rigidity relative to Bearing Arrangements III and IV.

Applications: NC Lathe, NC Milling Machine, Machining Center, etc.

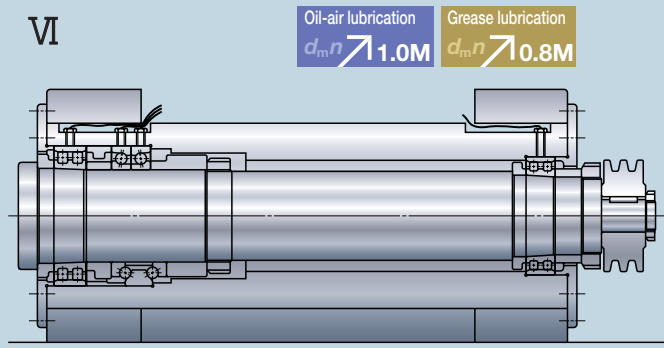

**Bearing Arrangement VI**

Front side: High rigidity double row cylindrical roller bearing, angular contact ball bearing duplex sets (DB)  
Rear side: High rigidity double row cylindrical roller bearing

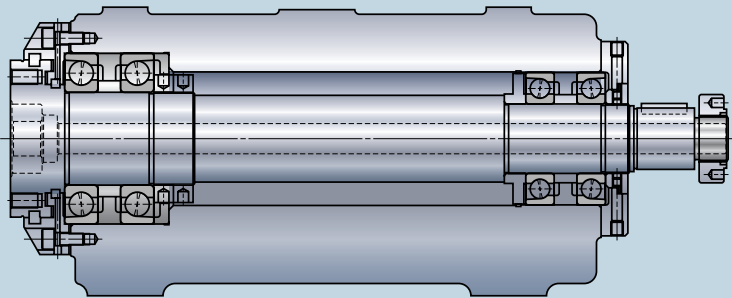

Although spindles with this arrangement have lower speed capability, the radial and axial rigidity of these spindles are highest.

Applications: NC Lathe, NC Milling Machine, Machining Center, etc.

Work Head Spindle

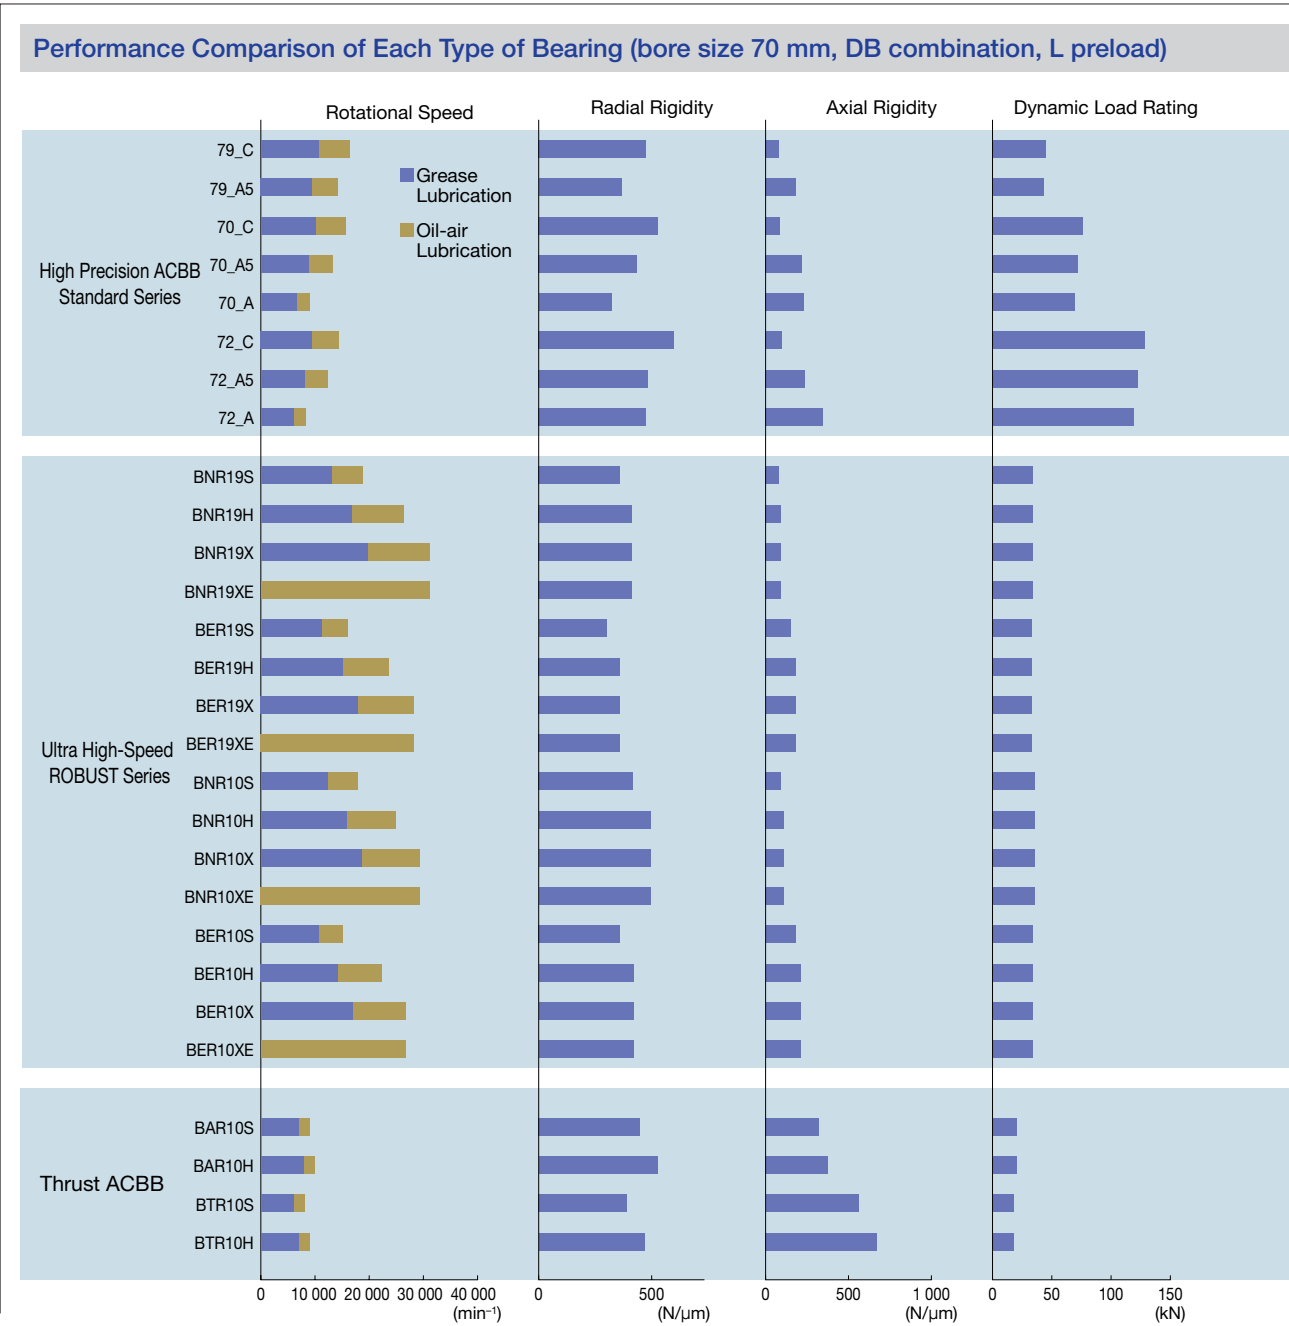

The main features of the Angular Contact Ball Bearing (ACBB)

- A predefined contact angle
- They are used in matched combinations with preload

In selecting Angular Contact Ball Bearings, it is important to consider the above two features, as each angular control ball bearing has specific features and performance.

Be sure to carefully consider the effects of changes in contact angle and preload on performance so that you select the ACBB that is best suited to the application. The following graphs summarize the relative performance of each type of ACBB (by series and dimensional series), depending on the contact angle, preload, and combination.

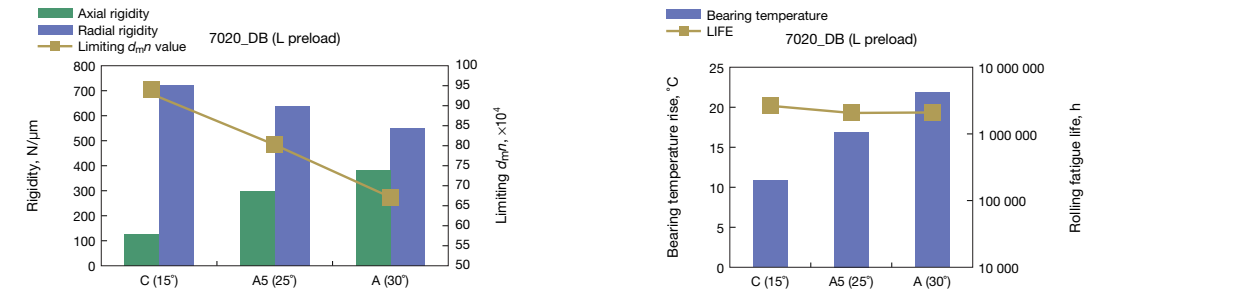

The Effect of Contact Angle

As the contact angle increases, Angular Contact Ball Bearings have a higher axial load capacity, but a lower speed capability. Thus, the ACBB with a smaller contact angle is better suited for high speed and high radial load applications.

The figure below compares the rigidity, limiting speed and temperature rise of a 7020 Angular Contact Ball Bearing with different contact angles: C angle (15°), A5 angle (25°) and A angle (30°).

Under the same light preload level (L), the bearing with C angle has higher radial rigidity with lower temperature rise relative to the bearing with A angle. The bearing with A angle has the highest axial rigidity, three times higher than that of the bearing with C angle, but the limiting speed is lower than the others.

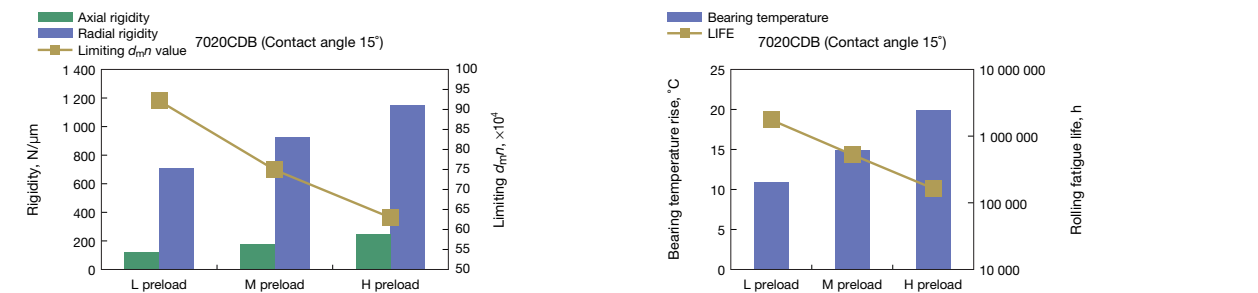

The Effect of Preload

Preload affects performance of ACBBs in much the same way that the contact angle does. As preload increases, the rigidity increases but the speed capability decreases. NSK has defined standard preload levels as Extra Light (EL), Light (L), Medium (M) and Heavy (H).

The figure below compares the performance of a 7020CDB with each preload level. Even if the contact angle is held constant, when the preload is larger, both axial and radial rigidity are increased. However the temperature also rises, so the limiting speed and calculated life become lower.

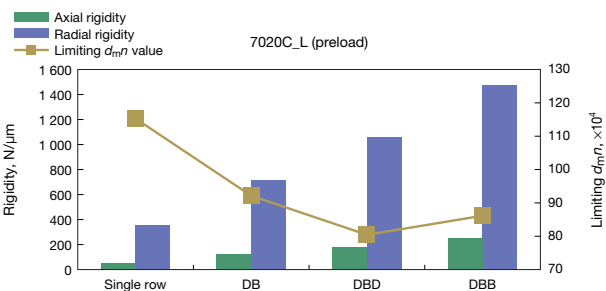

In order to maintain high rigidity, it is necessary to sacrifice higher speed. Similarly to accomplish higher speed, it is necessary to sacrifice high rigidity. Caution must be exercised. If too high a preload is combined with high operation speed, there is a possibility of seizure.

The Effect of Combination

ACBBs are usually used as multiple bearing sets. There are three types of combinations—Back-to-Back (DB), Face-to-Face (DF) and Tandem (DT).

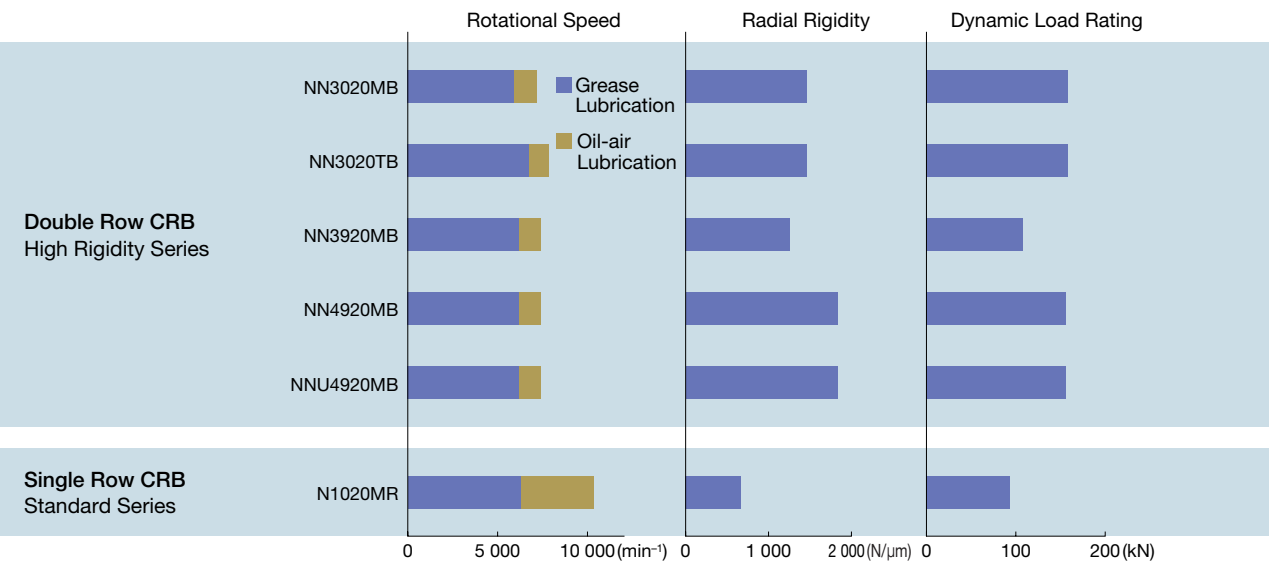

Two row, three row, and four row are the most popular multiple bearing sets. When the combination is held constant, and the number of rows is increased, the rigidity and the load capacity become larger, but the limiting speed becomes lower.

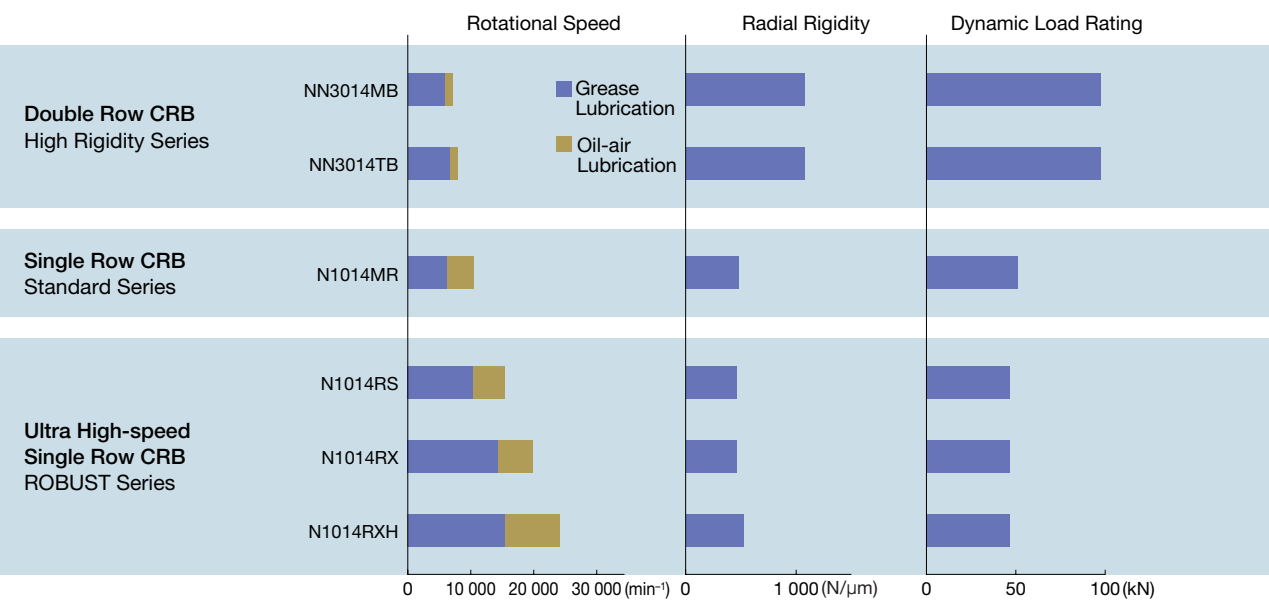

Cylindrical Roller Bearing (CRB)

- Cylindrical roller bearings support only radial loads, but have the advantage of a larger radial load capacity rating than ACBBs. Double row cylindrical roller bearings (NN and NNU types) and single row cylindrical bearings (N type) are available.
- In general, double row cylindrical roller bearings are used for high rigidity applications such as lathes, while single row cylindrical roller bearings are used in high-speed applications such as machining centers. The following graphs display cylindrical roller bearing performance depending on the type of bearing (by series and dimensional series) and the radial clearance involved.

Performance Comparison Relative to CRB Type: (bore size 100 mm)

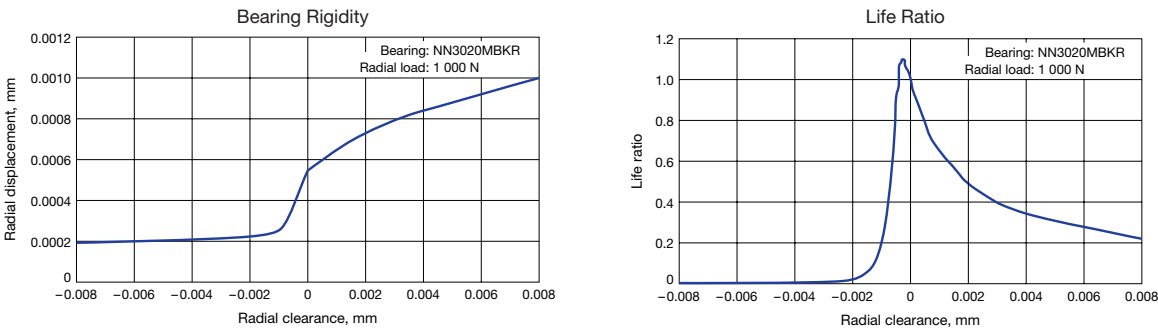

Performance Comparison Relative to CRB Type: (bore size 70 mm )

The Effect of the Radial Clearance

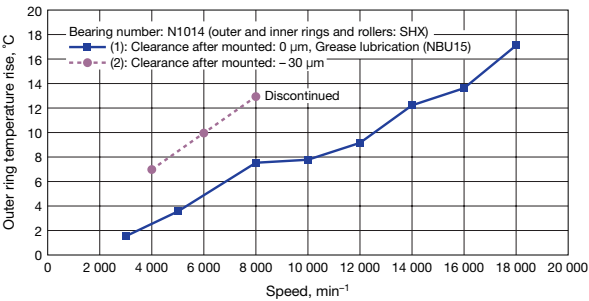

When using cylindrical roller bearings, it is important to control the radial clearance since it will have the greatest impact on bearing performance. As the radial clearance increases, both rigidity and calculated fatigue life decrease. With higher radial clearances heat generation during operation also decreases. Conversely, as the figure below illustrates, rigidity is not increased if the radial clearance drops below  $-0.003$  mm, while the calculated fatigue life continues to decrease. Therefore, the optimum clearance target to achieve high rigidity and long life is zero or just slightly negative clearance. For applications involving high speed, it is necessary to control the clearance during operation. Properly adjusting the radial clearance when the bearing is installed to compensate for the effects of high speed operation does this.

The Relationship Between Radial Clearance and Temperature Rise

The figure at the right shows test result of the temperature rise of CRB. After-mounted Radial Clearance  
Bearing (1):  $0\text{ }\mu\text{m}$   
Bearing (2):  $-30\text{ }\mu\text{m}$

The temperature rise of bearing (2) is larger and the limiting speed is lower than bearing (1), clearly demonstrating the importance of properly controlling the clearance.

A CRB with a tapered bore is used to control radial clearance during spindle assembly because it is easy to adjust the radial clearance to any value. For a CRB with a tapered bore, the popular unmounted noninterchangeable radial clearance classes are CC9, CC0, and CC1. The specific features of each are outlined below.

NSK's recommended clearance

- **CC0**  
Matched clearance range less than CC1. This range overlaps with the upper values of CC9 and lower values of CC1. As this clearance is easy for customers to target this range, it is the recommended clearance offered for CRB with taper bore.
- **CC1 clearance**  
Matched clearance range is greater than CC0. While not the standard, this clearance is most popular in the field. When clearance is at its maximum, special care is required to accomodate expansion of the inner ring. If care is not used, and the spindle's cross-section is thin, deformation of the bearing or shaft may occur.
- **CC9 clearance**  
Matched clearance range is less than CC0. This clearance will help avoid potential deformation of the inner ring or the shaft when there is little tolerance for inner ring expansion. Since the radial clearance is reduced to the minimum, the interference between the inner ring and the shaft becomes small. In high speed applications, this may cause loosening of the inner ring from the shaft and result in some creep damage.

Angular Contact Ball Bearings

High Precision Angular Contact Ball Bearings (Standard Series)

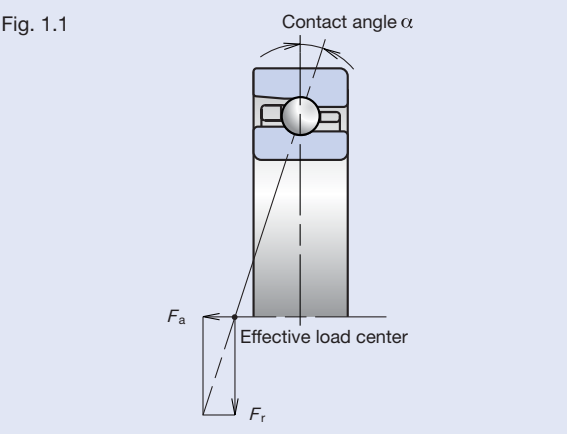

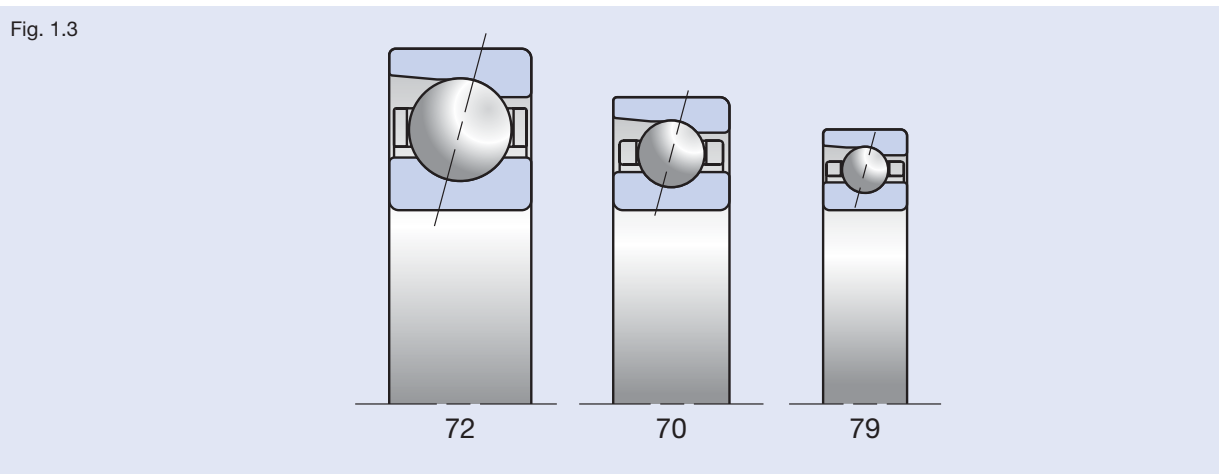

Features

Single-row angular contact ball bearings have a line connecting the contact points drawn in the radial direction, which is called the contact angle. The contact angle makes this bearing suitable for accommodating radial loads, single direction axial loads, and a combination of both. Furthermore, since an axial component is generated when a radial load is applied, these bearings are generally used in pairs, triplex sets, quadruplex sets, or multiplex sets.

Contact Angle

Dimension Series

When a load is applied to an angular contact ball bearing, elastic deformation and the amount of stress at the contact point changes as a result of the varying load conditions of the balls, inner ring, and outer ring according to the contact angle of the bearing.

Figure 1.2 illustrates loads acting on two rolling elements for a 30° contact angle, and a 15° contact angle. The relation between an axial load being applied to the bearing and resulting load acting on the rolling element can be formulated as:

$F_a / (\text{Number of balls} \times \sin \alpha)$

Therefore, the larger the contact angle, the smaller the load acting on the rolling element. Load at the contact point, and its consequential deformation, is reduced thus resulting in longer life. When a radial load is applied, the smaller the contact angle, the smaller the load acting on the rolling element, thus resulting in reduced load at the contact point.

(See Pages 42 and 43 for contact angle specifics.)

(¹) For permissible axial load, please refer to Page 147.  
(²) For application of limiting speeds, please refer to Page 170.  
When a ceramic ball is used, limiting speed value will be 1.25 times the value of steel ball.  
**Note:** Bearing numbers with a “C” suffix: nominal contact angle 15°  
Bearing numbers with an “A5” suffix: nominal contact angle 25°  
Bearing numbers with an “A” suffix: nominal contact angle 30°

1. ANGULAR CONTACT BALL BEARINGS

High Precision Angular Contact Ball Bearings (Standard Series)

70 Series

Bore Diameter 80-200 mm

Ultra High-Speed Angular Contact Ball Bearings (ROBUST Series)

Features

- Optimum Design

Robust design achieved with NSK's proprietary analytical technology.  
Optimum design achieved by computer simulation of temperature rise resulting from ball skid.
- Long Life

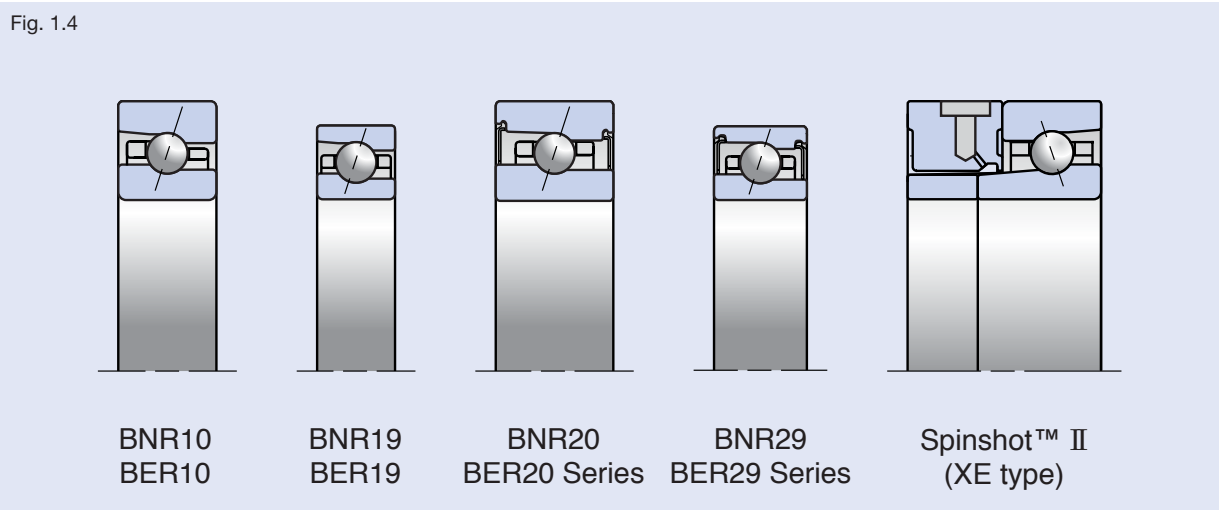

New SHX steel material provides superior heat and wear resistance.  
Enhanced service life measures include raising the seizure limit under low lubrication and high-speed operating conditions.
- High Accuracy

Rolling element material can be tailored to match the application.  
Ceramic balls are used for ROBUST series angular contact ball bearings.  
Highly accurate P2 series is available.  
NSK's experience and know-how ensure bearing specifications with a high degree of accuracy.
- High Speed

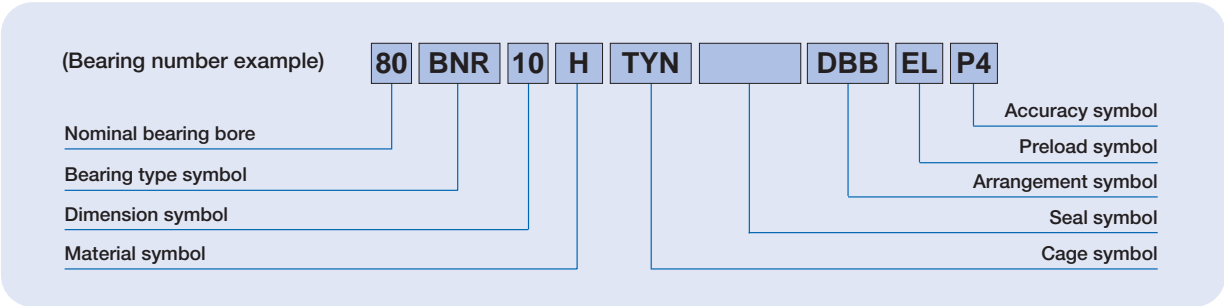

Cage engineered for high-speed operations.  
Benefits of the lightweight, high strength engineered resin cage include heat resistance and high rigidity, making this cage indispensable for high-speed applications.
- Low Noise

Quieter running high-speed spindle featuring Spinshot™ II lubrication system.  
Eliminates noise caused by compressed air of the oil-air lubrication system.

Dimension Series

(¹) For permissible axial load, please refer to Page 147.  
(²) For application of limiting speeds, please refer to Page 170.  
Note: Bearing type BNR: nominal contact angle 18°  
Bearing type BER: nominal contact angle 25°

1. ANGULAR CONTACT BALL BEARINGS

Ultra High-Speed Angular Contact Ball Bearings (ROBUST Series)

BNR19 Series  
BER19 Series

Bore Diameter 85-150 mm

For additional information:

● Dynamic equivalent load

● Static equivalent load

● Preload and rigidity

● Abutment and fillet dimensions

● Nozzle position

● Quantity of packed grease

## 1. ANGULAR CONTACT BALL BEARINGS

## Ultra High Precision Angular Contact Ball Bearings (ROBUST Series—BGR)

## Features

## Optimum Design

An outer ring guided cage is used to improve lubrication performance.  
The counter-bore inner ring improves oil-mist flow to ensure a stable oil supply.

Long Life

Special heat resistant SHX steel and ceramic balls significantly improve service life (X-type bearings).

## Easy Mounting

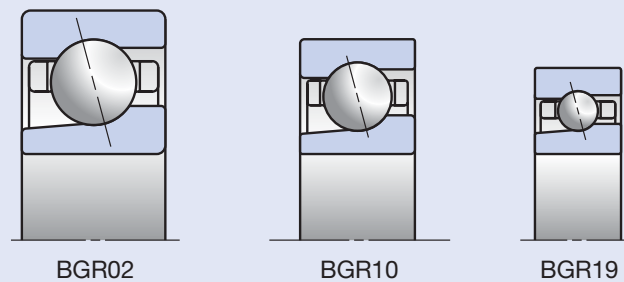

Non-separable inner ring design greatly simplifies mounting and dismounting procedures.  
Interchangeable assembly for any desired arrangement to meet customer needs.

## High Accuracy

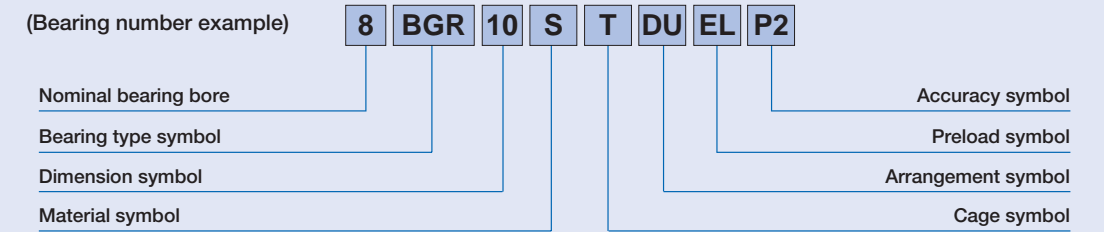

BGR Series are standardized for ISO Class 2 (ABMA ABEC 9).

## Dimension Series

Fig. 1.5

## Numbering System of Ultra High Precision Angular Contact Ball Bearings (ROBUST Series—BGR)

Cylindrical Roller Bearings

Cylindrical Roller Bearings

Features

The high rigidity of NSK’s double-row cylindrical roller bearings makes them a perfect match for use in machine tool spindles. Typically, single-row and double-row cylindrical roller bearings have either a cylindrical bore or a tapered bore. Double-row cylindrical roller bearings with a tapered bore are often mounted to the main shaft as a fixed-end bearing. Simplicity in design and the ability to adjust radial internal clearance after mounting continue to make these bearings popular among machine tool users.

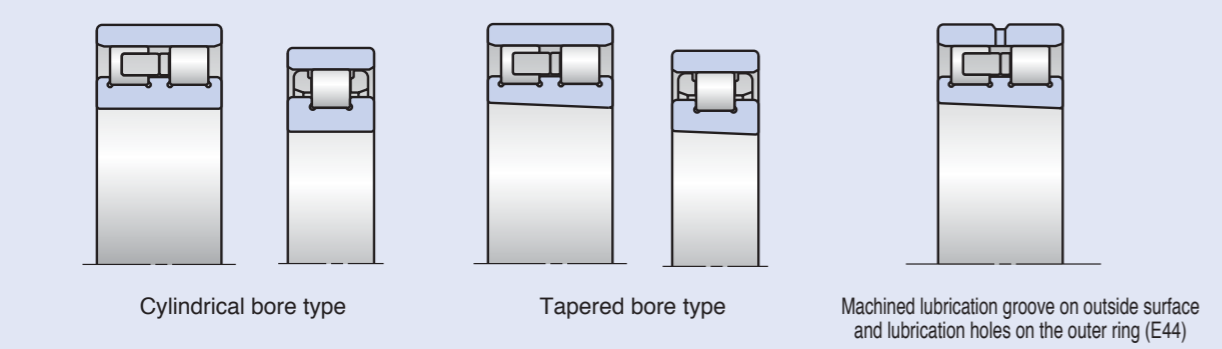

NSK offers several types of cylindrical roller bearings. Users can request an E44 configuration, which includes both lubrication holes and a machined lubrication groove on the outside surface of the outer ring. Types of bearings include the NNU type, which features double ribbed outer rings, and the NN type, which features excellent grease discharge during the initial running-in period, and helps promote steady oil flow throughout the bearing.

For thin section type bearings, the narrower NN39 series is more suitable than the wider NN49 series due to less heat generation and greater roller stability. Machined brass cages are most common with cylindrical roller bearings. NSK offers a roller guided PPS (polyphenylene sulfide) resin cage for the NN30 series, and a PEEK (polyether ether ketone) resin cage, which is guided by the outer ring, for N10 series of ultra high-speed single-row cylindrical roller bearings.

Bearing type	Cage symbol	Specification	Available size
NN	MB	Roller guided machined brass cage	NN3005, NN3026-NN3040 NN3920-NN3956 NN4920-NN4940
	TB	Roller guided PPS resin cage	NN3006-NN3024
NNU	MB	Roller guided machined brass cage	NNU4920-NNU4940
N	MR	Roller guided machined brass cage	N1006-N1028
	TP	Outer ring guided PEEK resin cage	N1009-N1017

Specification of Bore and Lubrication Holes

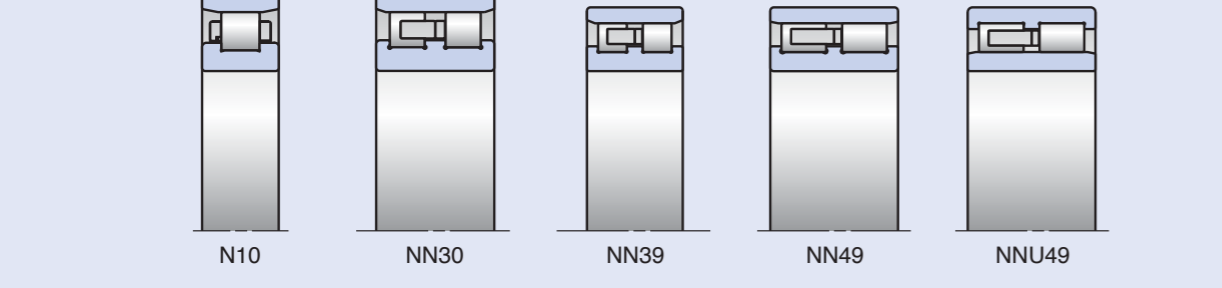

Fig. 2.1

Double-row and single-row bearings available with cylindrical bore or tapered bore.  
Double-row cylindrical roller bearings available with a machined lubrication groove and lubrication holes (the best solution for oil lubrication).

Angular Contact Thrust Ball Bearings

Features

For the main spindles of machine tools, good high-speed performance and high rigidity are required for the ball bearings used in combination with double-row cylindrical roller bearings. For these applications, to allow selection appropriate for the characteristics of the machine, NSK provides three types of bearings.

All these bearings have special outer ring outside diameter tolerances (P4A Class and P2A Class) to provide clearance between the outer ring periphery and housing bore in order to avoid any load. NSK's ROBUST series high-speed angular contact thrust ball bearings are capable of high-speed operations while maintaining high rigidity. Ball diameter and number of balls are the same as TAC type bearings. BTR type bearings have a 40° contact angle, and BAR type bearings have a 30° contact angle. The result is superior high-speed performance that minimizes heat generation.

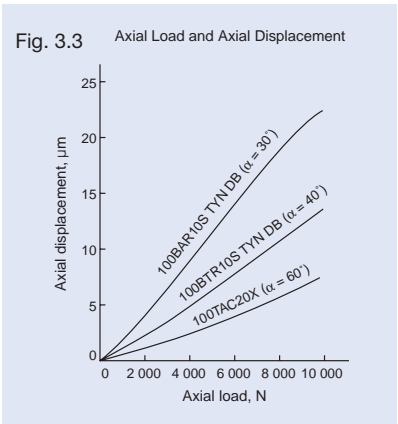

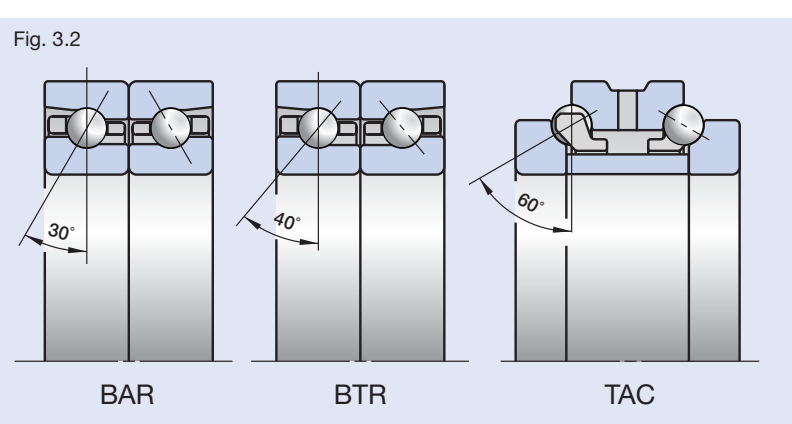

Interchangeability

Customers can easily replace their TAC20D series bearings with NSK's BAR type or BTR type bearings without having to change the shaft or housing of the machine tool spindle. Both types of bearings have unique width dimensions that accommodate a new spacer , which replaces the older one  (see Fig. 3.1).

Contact Angle

For the differing contact angles, TAC type bearings rank highest in levels of rigidity, closely followed by BTR type bearings, with BAR type bearings coming in last. For temperature rise of the outer ring, however, this ranking is reversed with BAR type bearings having the highest tolerance, followed by BTR type bearings, and finally TAC type bearings with the least tolerance. Be sure to select the product that will best meet the needs of your specific operating conditions.

Angular Contact Thrust Ball Bearings for Ball Screw Support

Features

High precision angular contact thrust ball bearings to support precision ball screws, have better performance than earlier combinations of angular contact ball bearings or combinations using thrust bearings. They are especially suitable for high precision machine-tool feeding mechanisms and similar applications.

TAC B Series (Machine Tool Applications)

The axial rigidity is high because of a large number of balls and a contact angle of 60°. Compared with tapered roller bearings of cylindrical roller bearings, this type has lower starting torque; so smoother rotation is possible with less driving force.

TAC B series bearings incorporate NSK’s recently developed molded polyamide resin cage. In addition, using extra-pure (EP) steel for the inner and outer rings has further enhanced service life. Our EP steel is manufactured by controlling the amount of harmful oxide inclusions, which eliminates large size inclusions and enjoys higher purity than vacuum arc remelted (VAR) steel. This series with “DG” seal, low torque contact seal, with “WPH” grease, an waterproof grease, increase the reliability and provide for easy handling.

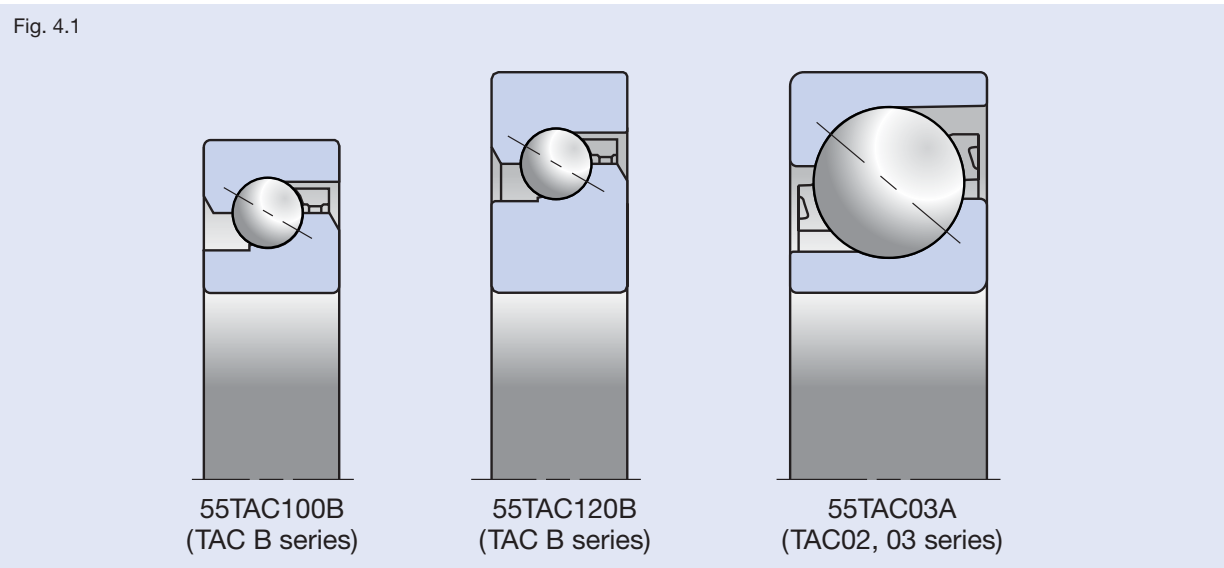

TAC02 and 03 Series (Electric Injection Molding Machines)

TAC02 and 03 series are angular contact ball bearings that provide support for large size ball screws operating under a heavy load from the driving mechanism of electric injection molding machines. Low torque is achieved by optimum design of the ball bearings. Users can significantly reduce bearing torque by replacing their roller bearings with these series.

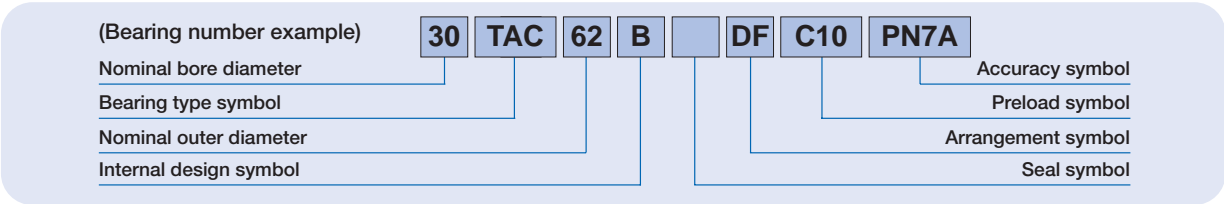

TAC B and TAC02, 03 Differences

Electric injection molding machines produce a heavier load on ball screw support bearings than that of machine tools. TAC02 and 03 bearings are designed to operate under such heavy load conditions. Conversely, TAC B bearings are designed for increased permissible load by increasing the number of balls and bearing width.

Units for Ball Screw Support

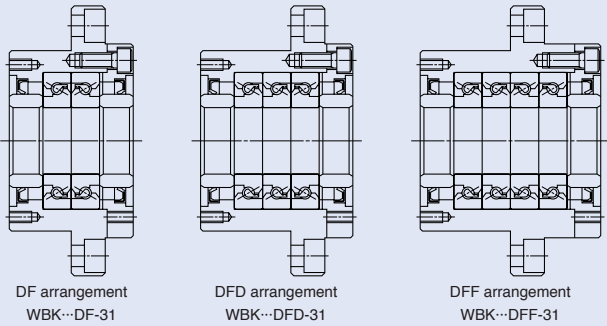

The support unit for heavy-load machine tools employs a high precision, high rigidity Angular contact thrust ball bearing for Ball Screw Support (TAC Series), which is structured to function optimally as a support bearing for a ball screw.

Three types of arrangements are available, as described in the figure below:

Features

- The dust-resistant design allows a user to easily design support side of ball screw.
- Since a preload-controlled bearing is incorporated into the support unit, the process of mounting a bearing can be omitted.

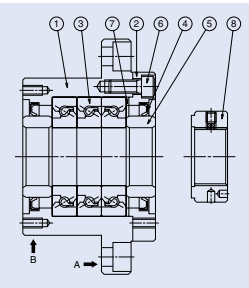

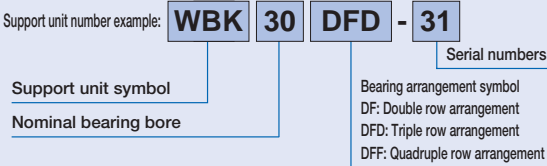

Support Unit Numbers	Support Unit Parts																
	d	D	D <sub>1</sub>	D <sub>2</sub>	L	L <sub>1</sub>	L <sub>2</sub>	A	W	X	Y	Z	d <sub>1</sub> *	I*	V*	P*	Q*

WBK40DFD-31					81	48											
WBK40DFF-31					96	48											

Remarks: 1. Rigidity:  
Rigidity values in the table show theoretical values calculated from elastic displacement between grooves and steel balls.

2. Starting torque:  
Starting torque in the table shows starting torque necessary for a preloaded bearing, not including seal torque.

3. Tolerance of Shaft Outer Diameter at the bearing seat for unit:  
h5 Class is recommended for the Shaft Outer Diameter at the bearing seat for unit.

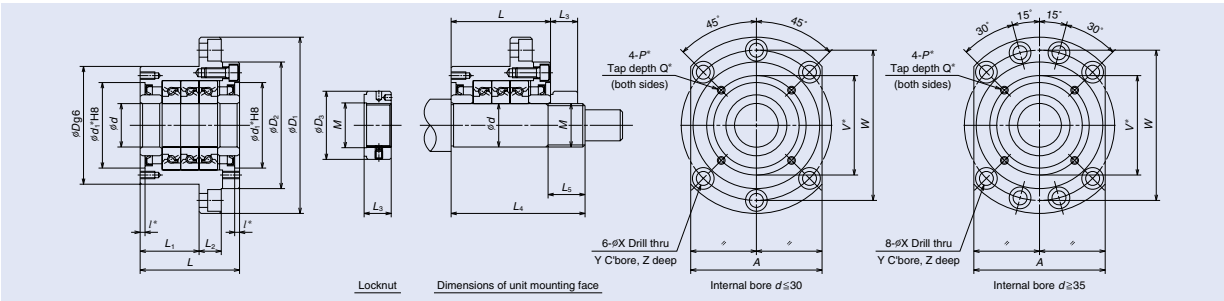

Numbering system of support units

Components of support unit

Part No.	Name of Part	Quantities
①	Housing	1
②	Retaining cover	1
③	Angular contact thrust ball bearings for Ball Screw Support	1 set
④	Dust seal	2
⑤	Collar	2
⑥	Preload securing bolt	6 or 8
⑦	Shim	1 set
⑧	Locknut	1

1. Use datum faces A and B to mount the support unit to a machine base.
  2. Do not try to disassemble the NSK Support Unit because its preload is adjusted with high precision and the components of numbers ①, ②, ③, ④, ⑥ and ⑦ are integrated into a single piece.
  3. Grease is packed in the bearing.
  4. Locknut ⑧ is designed specifically for ball screws with its perpendicularities controlled against the triangular thread of the screw.
- To prevent loosening, tighten the locknut using turn-preventive small screws.
- The locknut is also available separately. For Angular contact thrust ball bearings for Ball Screw Support, please refer to Page 110.

Basic dynamic load rating C <sub>a</sub> (N)	Limiting Axial Load (N)	Preload (N)	Axial Rigidity (N/μm)	Starting torque (N·cm)	Locknut			Bearing seat for unit

31 500	52 000	3 900	1 230	28.0	M40· 1.5	60	22	40	92	30
51 500	104 000	5 300	1 810	38.0					107	
51 500	104 000	7 800	2 400	57.0					122	

Remarks: 4. Dimensions marked with \*  
The spigot and screw parts marked with \* are used for mounting a seal unit for the NSK standard hollow ball screw shaft as well as for mounting a dust cover and damper.

5. Because grease is packed in the bearing, it can be used immediately as is.

Precision Deep Groove Ball Bearings

Polyamide Resin Cage

Precision Deep Groove Ball Bearings

Precision Deep Groove Ball Bearings .....P118-120

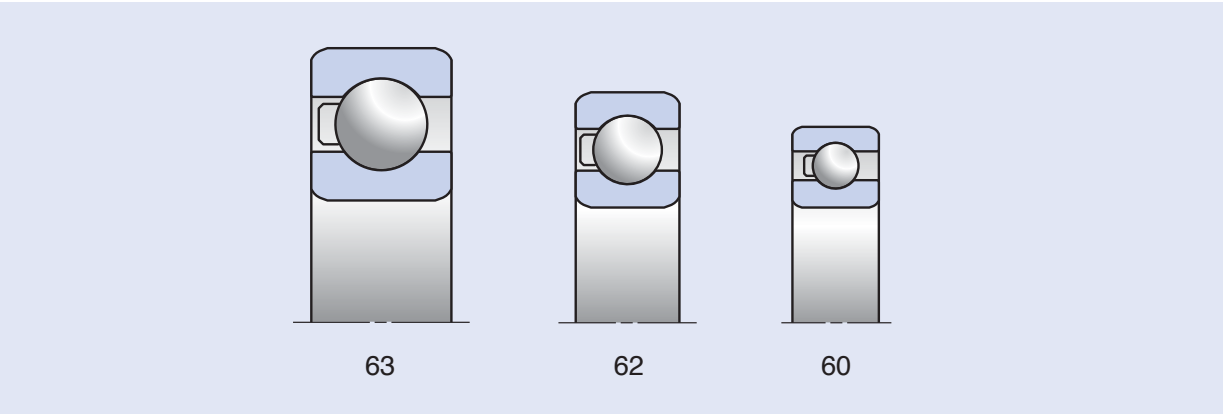

- Features
- Numbering System
- Bearing Tables
  - T1X Type (Polyamide resin cage)
  - 60, 62 and 63 Series

Precision Deep Groove Ball Bearings

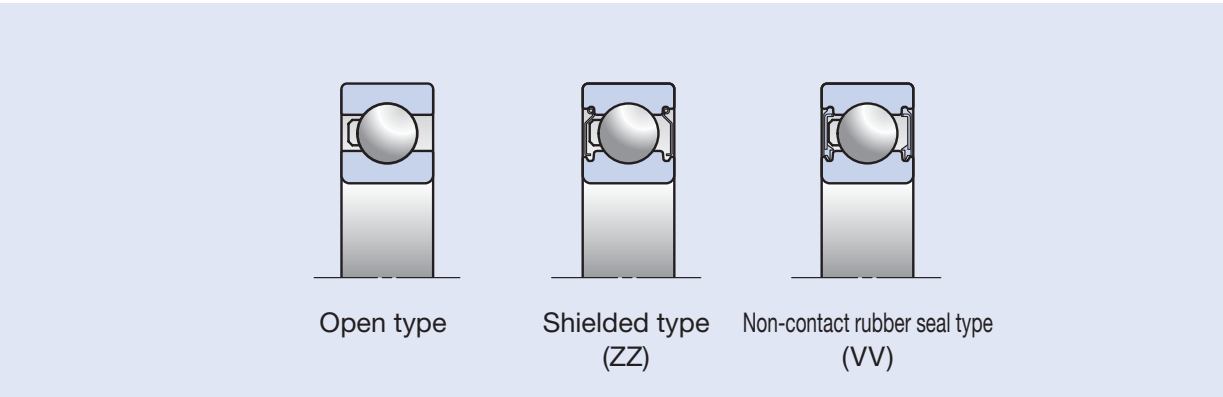

Features

- Capable of bearing not only radial loads but also axial loads in both directions.
- Frictional torque is small, thus suitable for operations requiring high speed, low noise, and low vibrations.
- Three types are available: open type; shielded type (steel shield); and sealed type (rubber seal).

Dimension series

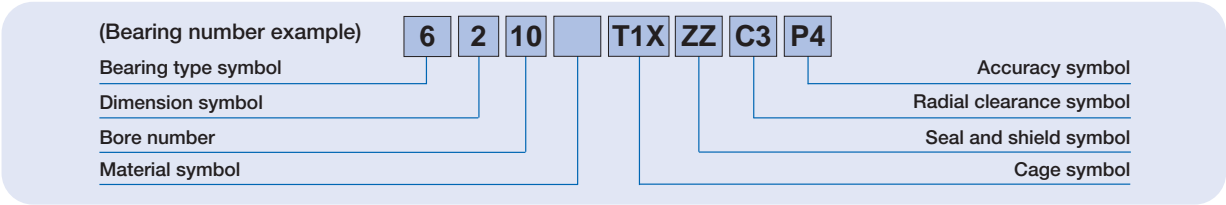

Structure

Cages

- T1X** Ball guided polyamide resin cage: provides superior wear resistance for general purpose motors.
- TYA** Ball guided polyamide resin cage: incorporates the same design concepts of angular contact ball bearings for high-speed motors.

Ring Gauges GR Series

Housing bore diameter precision measuring gauges

To obtain satisfactory performance of precision rolling bearings for machine tool spindles, it is important to have an accurate fitting with the shaft and housing.

To achieve an accurate fitting, it is necessary to measure the shaft outside diameter and housing bore exactly.

NSK Ring Gauges GR series are master gauges for measuring the bore diameters of housings within an accuracy of 0.001 mm.

Features

- Ring design enables reliable cylinder gauge settings.
- Ring thickness eliminates any deformation caused by measuring pressure.
- Heat treatment during manufacturing of the ring negates any effects of aging on ring dimensions.
- Exact gauging is possible due to precisely measured dimensions that are marked on the gauges in 0.001 mm units in both the X and Y directions.

Taper Gauges GTR30 Series

Shaft taper measuring gauges

NN30XXKR are tapered bore, double row cylindrical roller bearings that have high rigidity and are suitable for high speeds, so they are often used in machine tool spindles.

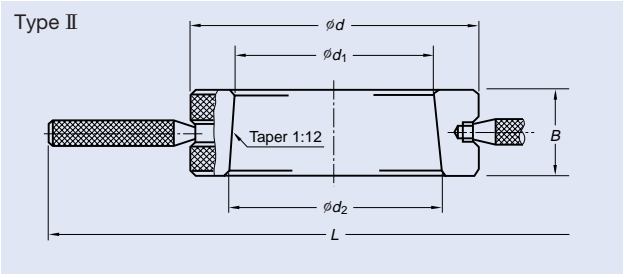

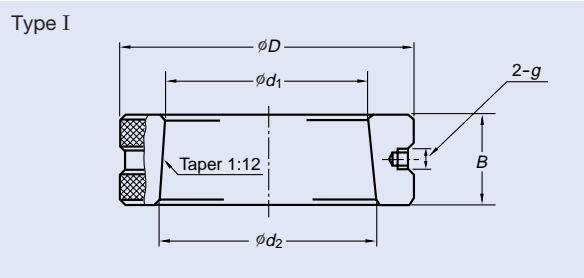

To use these bearings, it is important to exactly match the taper of the bearing bore with that of the spindle. The bearing taper (taper 1:12) is precisely controlled and manufactured for a specific accuracy.

A Tapered Gauge

GTR30 is one whose bore is precision finished with a taper identical with that of a bearing. By machining the taper of a spindle to match this taper gauge, its exact contact with the bearing is assured.

Features

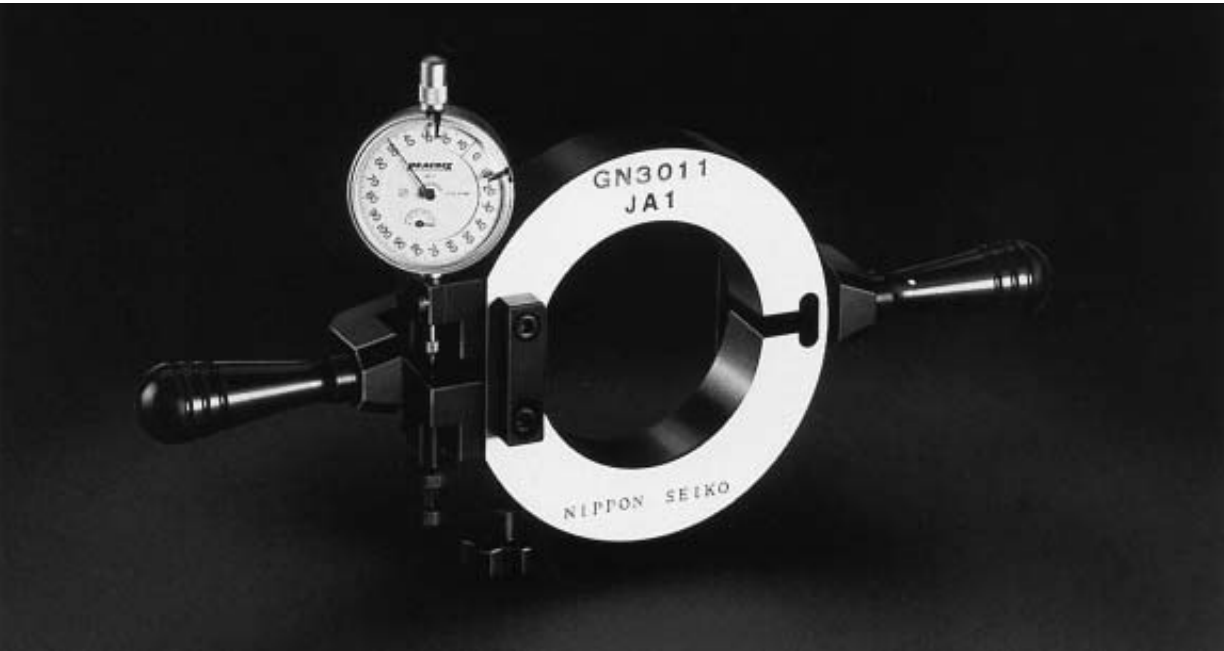

- Ring thickness eliminates any deformation caused by measuring pressure.
- Heat treatment during manufacturing of the ring negates any effects of aging on ring dimensions.

GN gauges GN30 Series

Precision measuring gauges for residual radial clearance of double-row cylindrical roller bearings (NN30XX)

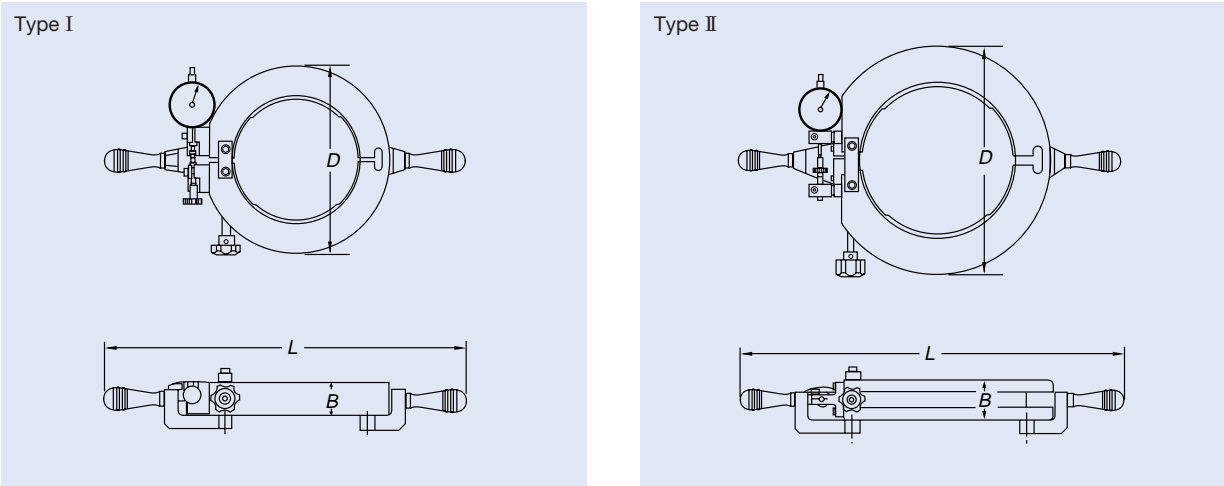

When mounting a double-row cylindrical roller bearing with a tapered bore onto a shaft, it is important to accurately match the spindle taper with that of the bearing, and to ensure that the desired radial internal clearance is attained after mounting.

If there is excessive residual radial internal clearance, the main shaft will have some play and machining accuracy will be adversely affected. If clearance is too small, despite little or no change in rigidity, heat generation will become excessive and rolling fatigue life will be extremely shortened (See page 155).

With the recent trends toward higher speed and higher precision, it is necessary to control residual radial internal clearance more carefully. In the past, radial clearance measuring methods were very difficult and required much skill. GN gauges developed by NSK for residual radial internal clearance measurements of double-row cylindrical roller bearing simplify bearing mounting and improve mounting accuracy. (Use of GN gauges also require a bore measuring cylinder gauge.)

- Features**
- Simple, reliable, and accurate measurements can be made.
  - No more complicated calculations for corrections based on interference of an outer ring with housing.
  - Both positive and negative clearance (preload) can be measured.
  - Accurate measurements are obtained since all GN gauges are calibrated for measuring pressure.

Bearing Monitor NB-4

Microelectronics allow the NB-4 Bearing Monitor (a vibration monitor) to be a conveniently portable size. With high sensitivity and a variety of functions built in, it can quickly and reliably detect unusual vibrations in bearings or machines, and warn of possible trouble.

Features

- Vibrations can be measured and recorded and then displayed as a waveform (recorded by a personal computer or other device).
- The envelope function of the NB-4 makes it possible to detect any damage on the raceway of a bearing.

**NB-4 Main Body**

Warning light  
LED flashes if isolated bearing flaws exist.

Function Switch  
To select displacement, velocity, or acceleration.

Mode Switch  
To select rms or peak readings and output signals.

Sensitivity Switch  
To select high or low sensitivity or turn power off.

Helical Cable  
A tangle-free, extendable cable may be used to connect the vibration pick-up, or it can be connected directly to the main body.

Helical Cable connected to hand-held probe

Optional fixed pick-up  
Held by magnet or screw (waterproof)

**Probe Type Pick-up**

Hand-held Vibration Pick-up  
Superior high-frequency response allows early detection of trouble in bearing and other machine parts.

NB-4 Main Body connected to hand-held Vibration Pick-up

Liquid Crystal Display  
Vibration data are shown. Low battery voltage, excessive input, and PEAK mode selection are also indicated.

Hold Button  
Displayed vibration data (LCD) is held constant.

Earphone Output  
Vibrational sound may be heard using earphones and the volume controller.

Output Terminal  
Displays either a vibration waveform or a waveform envelope signal.

Bearing Heater

A bearing heater heats a bearing evenly and quickly to fit the bearing on a spindle, thus enabling clean mounting without oil. A bearing heater can be used to heat not only bearings but also ring-shaped metal parts, such as gears.

Features

- Rapid and even heating
- No heating oil is required, thus there is no greasy dirt.
- Suitable for shrinkage fit of bearings as well as ring-shaped metal parts.

User-friendly operation panel

In conjunction with an ultra-compact high sensitive temperature sensor, the heater indicates precise, real-time temperatures through digital display, irrespective of heating speed or detection area. The heater starts or stops at the flick of a button. The timer can be set for a maximum of 100 minutes. \*External input/output terminals for remote control on-line are featured as standard, enabling factory automation as well.

A superior level of safety

The heater automatically stops promptly if heat is applied without setting the temperature sensor or in the event of a device failure.

Compatible with various sizes of bores

By selecting an I-type core that matches the bore of a bearing, one bearing heater can be compatible with bearings of various sizes.

Automatic heating under optimal conditions

Electrical properties change depending on the type of bearing and I-type core used. The heater automatically detects these changes and thus always applies heat optimally. Also, as the output is adjustable from 50% to 100% in increments of 10%, the heater is ideal for delicate bearings that require gradual heating.

Grease Replenishing System FINE-LUB II

Until recently, high-speed spindles have used oil-air or oil-mist lubrication. Current worldwide concern for the environment requires a new system that reduces noise and oil mist while supporting clean working environment and energy saving. In response to this demand, NSK has developed FINE-LUB II, the world's first grease-replenishing system for high-speed machine tool spindles.

FINE-LUB II feeds a small amount of grease into high-speed bearings at regular intervals and discharges old grease, through an optimally shaped spacer, to a grease storage located in the housing. This technology delivers the world's first grease lubrication system for the high-speed spindles of machine tools and, at the same time, increases the operating lifetime. This revolutionary product completely transforms the concept of grease lubrication. FINE-LUB II leads the way to a new type of grease lubrication, making it faster, accurate, and more comfortable.

Features

Longer operating life for lubricating grease

The operating lifetime of grease is several hundred hours during continuous rotation at a speed of 1.8M  $d_m n$  (#40 taper 20 000 min<sup>-1</sup>). FINE-LUB II has been developed with the aim of feeding in an appropriate amount of grease depending upon the rotation speed and bearing size to avoid seizure, thereby ensuring more than 10 000 hours of maintenance-free performance.

Controlling the discharge of lubricating grease to prevent temperature increase.

Feeding too much grease into the inside of a bearing can cause the temperature to increase due to grease churning. To prevent this, FINE-LUB II features a built-in device to ensure that an appropriate amount of grease is discharged.

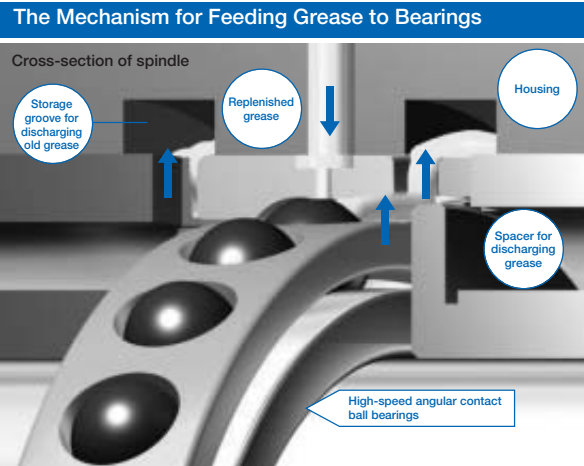

Bearing shape designed specifically for grease replenishing

● Grease replenishing method

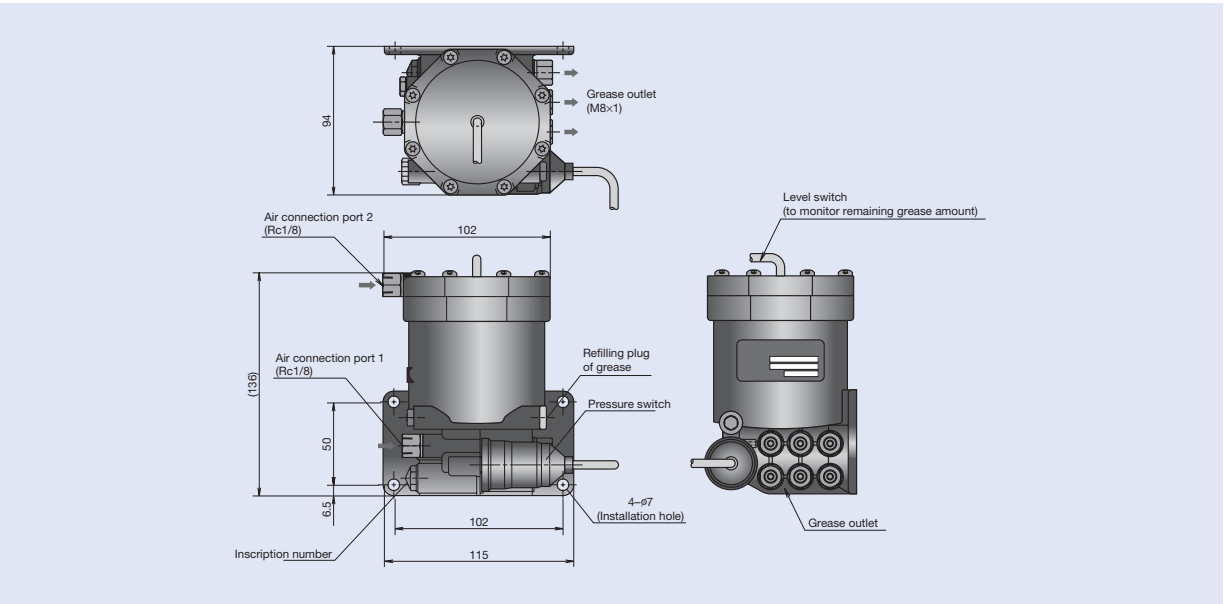

A small amount of grease is fed into a rotating bearing at regular intervals through a grease inlet located near the outer ring raceway. The grease is fed in small amounts to prevent the bearing temperature from increasing.

● Grease discharging method

A specially shaped spacer for grease discharge, located at the counter-bore side of the bearing, directs old grease into a storage groove, preventing it from re-entering the inside of the bearing.

## 6. PERIPHERAL EQUIPMENT

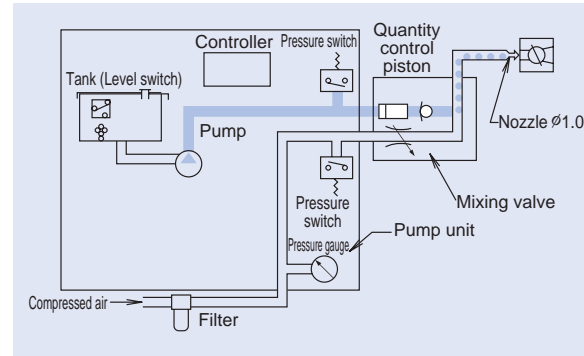

■ FINE-LUB Oil-Air Lubricator

## Features

Remarkable technological innovations continue in the field of machine tools. Particularly, spindle motors are operating faster than before. New developments for improving bearing and lubrication methods to facilitate the higher speeds are therefore vital.

NSK has made many developments in oil-air lubrication systems and oil supply equipment. In 1984, NSK introduced the FINE-LUB oil-air lubricator to the market, and continues to enjoy success with this product. The FINE-LUB has evolved with the times, and has been adopted for use in many machine tools, while earning a reputation for excellent performance and high reliability.

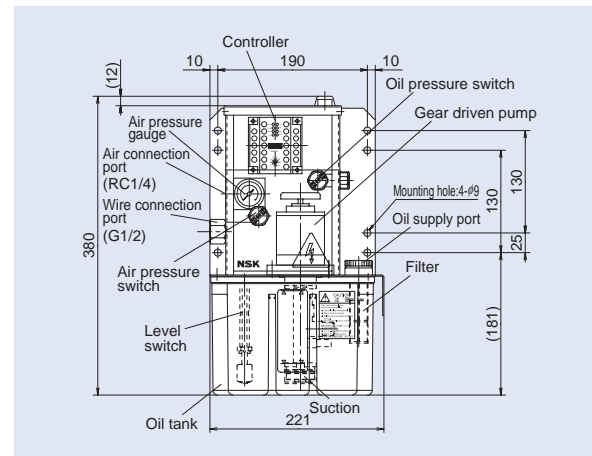

The FINE-LUB oil-air lubricator has a leading position in the oil-air lubrication market. This unit provides oil-air lubrication by a system, which consists of a pump, mixing valves, and a control unit. Reliability has been further improved by incorporating safety devices.

[Precautions]

- Use clean, dry compressed air at a pressure of 0.2–0.4 MPa.
  - Use fresh, clean lubricating oil with a viscosity of ISO VG 10 or higher.
- Please take extra care to avoid oil contamination, which can shorten the life of equipment.
- Take extra care in selecting quality oil lines for use between the pump and mixing valves. Oil lines exceeding 5 m in length require you contact NSK prior to use.
  - Oil lines from the mixing valve to the spindle should be limited to 1.5–5 m.

■ OAEM Pump Unit

## Features

- The OEM unit is a newly developed low viscosity gear driven pump.  
(Operating oil viscosity range: 10–68 mm<sup>2</sup>/s)
- A special controller is used to set lubricating intervals at 1, 2, 4, 8, 16, 24, 32, 48, 64, or 128 minutes.
- Standard safety devices include:
  - ① Oil level switch
  - ② Power failure warning
  - ③ Air pressure switch
  - ④ Oil pressure switch

Model number:  
 OEM (Incl. controller)  
 OEM-N (No controller)

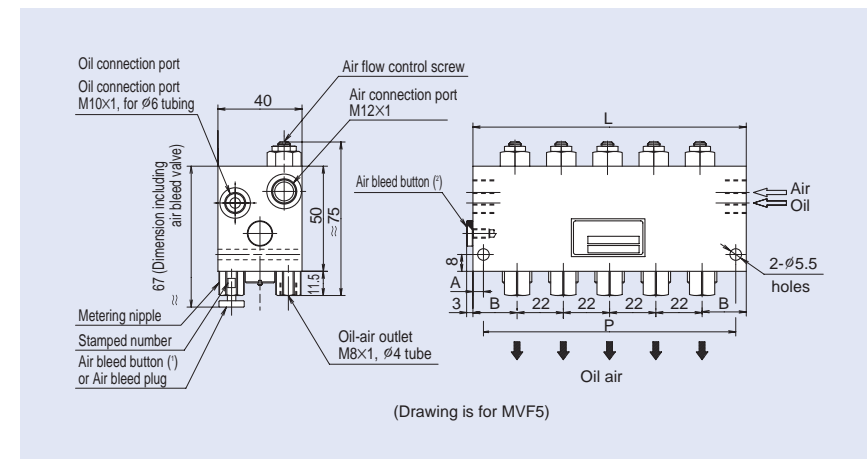

- Lubrication: high speed spindle oil, or turbine oil
- Power supply: 100 V
- Tank capacity: 2.7 L
- Effective oil level: 1.7 L

- Components of pump unit: Controller, air pressure switch, Oil pressure switch and Float switch.

NSK also offers a more economical pump unit that is CE Mark approved.

This pump can be controlled exclusively by our controller, or by a machine equipment sequencer.

- **Mixing Valve MVF**

## Features

- Adopts a piston-type control for discharging small, fixed quantities of oil.
- Discharged quantities of 0.01, 0.03, and 0.06 cm<sup>3</sup> per stroke can be selected.
- Number of outlets and discharge quantities can be selected depending on each condition.

**Notes** (1) In case the discharged quantity is 0.01 cm<sup>3</sup>, use Air bleed plug for Air bleed procedure.

In case the discharged quantity is 0.03 cm<sup>3</sup>, or 0.06 cm<sup>3</sup>, attach Air bleed button instead of Air bleed plug, for Air bleed procedure.

(2) In case the discharged quantity is 0.03 cm<sup>3</sup>, or 0.06 cm<sup>3</sup>, attach the Air bleed button to this position, during the operation.

Type number	Number of valves	L	A	P	B
MVF1	1	42	10	22	21
MVF2	2	64	9.5	45	21
MVF3	3	86	8	70	21
MVF4	4	108	6.5	95	21
MVF5	5	130	5	120	21
MVF6	6	155	5	145	22.5

Discharge quantity (cm³/stroke)	Stamping number	Code number
0.01	1	P1
0.03	3	P2
0.06	6	P3

## ■ Optional Parts

[Pressure switch]

OAG

- Monitors for increases in air and oil pressure and drop in oil pressure. (Equipped on OAEM)

[Oil Filter]

## OAV-02/03

- Filters remove minute foreign particles from the oil.
- Two types are available: 3  $\mu\text{m}$  and 20  $\mu\text{m}$

[Oil-Air Sensor]

- The oil-air sensor makes it possible to improve the reliability of oil-air lubrication by monitoring oil particles supplied from a mixing valve to a bearing.
- The device can be added later to an existing oil-air system by connecting the device to an oil-air pipe.

[Air Bleed Valve]

## OAV-01

- Bleed valves facilitate bleeding air after disconnecting oil lines for maintenance of the lubricator.

Sealed Precision Spacers for Machine Tool Spindles

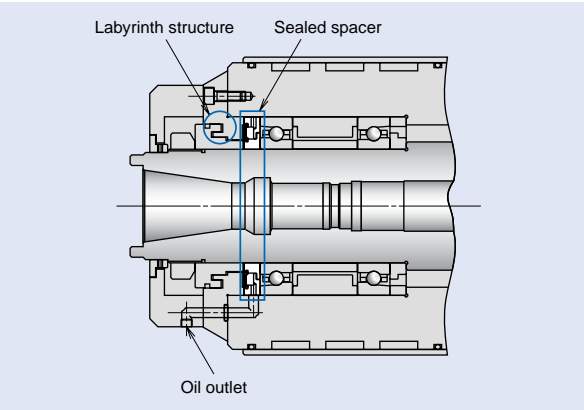

Features

In the past, labyrinth spacers were used to prevent foreign matter from entering a bearing in a spindle. However, because the clearance between inner and outer spacer rings is large, the entry of foreign matter cannot be completely prevented. NSK succeeded in narrowing the gap between them by attaching seals to spacers. The double structure of a labyrinth spacer plus a seal improves the reliability of the spacers.

- Environmentally-sound  
Attached seals prevent the leakage of grease
- Enhanced reliability  
For grease lubrication, a double-layer structure of a labyrinth spacer plus a seal provides superior resistance against entry of dust and coolant.

The example in the figure on the left contains a triple-seal configuration—the labyrinth seal which consists of the retaining cover and the inner-ring spacer provide the first seal, followed by the sealed precision spacer with an additional built-in labyrinth seal.

Specification

Material for outer-ring spacer	SUJ2
Material for inner-ring spacer	SUJ2
Seal material	Nitrile rubber, SECC

Handling precautions

Note that an inner-ring spacer and an outer-ring spacer can be separated, so take care that rubber seal do not fall out or sustain damage during handling.

Use universal combination bearings (see pages 150-151) with sealed precision spacers.

Rolling Fatigue Life and Basic Load Rating  
Bearing Life

The various functions required of rolling bearings vary according to the bearing application. These functions must be performed for a prolonged period. Even if bearings are properly mounted and correctly operated, they will eventually fail to perform satisfactorily due to an increase in noise and vibration, loss of running accuracy, deterioration of grease, or fatigue flaking of the rolling surfaces.

Bearing life, in the broad sense of the term, is the period during which bearings continue to operate and to satisfy their required functions. This bearing life may be defined as noise life, abrasion life, grease life, or rolling fatigue life, depending on which one causes loss of bearing service.

Aside from the failure of bearings to function due to natural deterioration, bearings may fail when conditions such as heat-seizure, fracture, scoring of the rings, wear of the seals, or other damage occurs. Conditions such as these should not be interpreted as normal bearing failure since they often occur as a result of errors in bearing selection, improper design or manufacture of the bearing surroundings, incorrect mounting, or insufficient maintenance.

Rolling Fatigue Life and Basic Rating Life

When rolling bearings are operated under load, the raceways of their inner and outer rings and rolling elements are subjected to repeated cyclic stress. Because of metal fatigue of the rolling contact surfaces of the raceways and rolling elements, scaly particles may separate from the bearing material.

This phenomenon is called “flaking”. Rolling fatigue life is represented by the total number of revolutions at which time the bearing surface will start flaking due to stress. This is called fatigue life. Even for seemingly identical bearings, which are of the same type, size, and material and receive the same heat treatment and other processing, the rolling fatigue life varies greatly, even under identical operating conditions. This is because the flaking of materials due to fatigue is subject to many other variables. Consequently, “basic rating life”, in which rolling fatigue life is treated as a statistical phenomenon, is used in preference to actual rolling fatigue life.

Suppose a number of bearings of the same type are operated individually under the same conditions. After a certain period of time, 10% of them fail as a result of flaking caused by rolling fatigue. The total number of revolutions at this point is defined as the basic rating life or, if the speed is constant, the basic rating life is often expressed by the total number of operating hours completed when 10% of the bearings become

inoperable due to flaking.  
In determining bearing life, basic rating life is often the only factor considered. However, other factors must also be taken into account. For example, the grease life of grease-prelubricated bearings can be estimated. Since noise life and abrasion life are determined according to individual standards for different applications, specific values for noise or abrasion life must be determined empirically.

Basic Dynamic Load Rating

The basic dynamic load rating is defined as the constant load applied on bearings with stationary outer rings that the inner rings can endure for a rating life of one million revolutions (10<sup>6</sup> rev). The basic load rating of radial bearings is defined as a central radial load of constant direction and magnitude, while the basic load rating of thrust bearings is defined as an axial load of constant magnitude in the same deflection as the central axis. The load ratings are listed under *C<sub>r</sub>* for radial bearings and *C<sub>a</sub>* for thrust bearings in the dimension tables.

Basic Rating Life

The following relation exists between bearing load and basic rating life:

For ball bearings

$$L_{10} = \left(\frac{C}{P}\right)^3$$
$$L_{10} = \frac{10^6}{60n} \left(\frac{C}{P}\right)^3 \quad (\text{h})$$

For roller bearings

$$L_{10} = \left(\frac{C}{P}\right)^{10/3}$$
$$L_{10} = \frac{10^6}{60n} \left(\frac{C}{P}\right)^{10/3} \quad (\text{h})$$

where

*L<sub>10</sub>* : Basic rating life (10<sup>6</sup> rev, or h)  
*P* : Bearing load (equivalent load) (N)  
(Refer to Page 125)  
*C* : Bearing dynamic load rating (N)  
For radial bearings, *C* is written *C<sub>r</sub>*  
For thrust bearings, *C* is written *C<sub>a</sub>*  
*n* : Rotational Speed (min<sup>-1</sup>)

In the case of bearings that run at a constant speed, it is convenient to express the fatigue life in terms of hours.

Dynamic Equivalent Load

In some cases, the loads applied on bearings are purely radial or axial loads; however, in most cases, the loads are a combination of both. In addition, such loads usually fluctuate in both magnitude and direction.

In such cases, the loads actually applied on bearings cannot be used for bearings life calculations; therefore, a hypothetical load should be estimated that has a constant magnitude and passes through the center of the bearing, and will give the same bearing life that the bearing would attain under actual conditions of load and rotation. Such a hypothetical load is called the dynamic equivalent load.

Assuming the equivalent radial load as *P<sub>r</sub>*, the radial load as *F<sub>r</sub>*, the axial load as *F<sub>a</sub>*, and the contact angle as *α*, the relationship between the equivalent radial load and bearing load can be approximated as follows:

$$P_r = XF_r + YF_a$$

where

*X* : Radial load factor  
*Y* : Axial load factor

} See Table 1.1

The axial load factor varies depending on the contact angle. In the case of roller bearings, the contact angle remains the same regardless of the magnitude of the axial load. In the case of single row deep groove ball bearings and angular contact ball bearings, the contact angle increases when the axial load is increased. Such change in the contact angle can be expressed by the ratio of the basic static load rating *C<sub>0r</sub>* and axial load *F<sub>a</sub>*. Table 1.1 shows the axial load factor at the contact angle corresponding to this ratio. Regarding angular contact ball bearings, the effect of change in the contact angle on the load factor may be ignored under normal conditions even if the contact angle is as large as 25°, 30° or 40°. For the thrust bearing with the contact angle of *α* ≠ 90° receiving both radial and axial loads simultaneously, the equivalent axial load *P<sub>a</sub>* becomes as follows:

$$P_a = XF_r + YF_a$$

Life Calculation of Multiple Bearings as a Group

When multiple rolling bearings are used in one machine, the fatigue life of individual bearings can be determined if the load acting on individual bearings is known. Generally, however, the machine becomes inoperative if a bearing in any part fails. It may therefore be necessary in certain cases to know the fatigue life of a group of bearings used in one machine.

The fatigue life of the bearings varies greatly and our fatigue life calculation equation  $L_{10} = \left(\frac{C}{P}\right)^3$  applies to the 90% life (also called the rating fatigue life, which is either the gross number of revolution or hours to which 90% of multiple similar bearings operated under similar conditions can reach).

In other words, the calculated fatigue life for one bearing has a probability of 90%. Since the endurance probability of a group of multiple bearings for a certain period is a product of the endurance probability of individual bearings for the same period, the rating fatigue life of a group of multiple bearings is not determined solely from the shortest rating fatigue life among the individual bearings. In fact, the group life is much shorter than the life of the bearing with the shortest fatigue life.

Assuming the rating fatigue life of individual bearings as  $L_1, L_2, L_3 \dots L_n$  and the rating fatigue life of the entire group of bearings as  $L$ , the below equation is obtained :

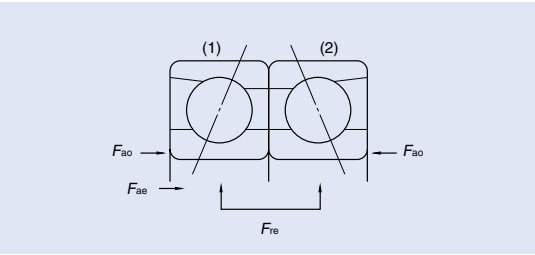

$$\frac{1}{L^e} = \frac{1}{L_1^e} + \frac{1}{L_2^e} + \frac{1}{L_3^e} + \dots + \frac{1}{L_n^e}$$

where, e = 1.1 (both for ball and roller bearings)

Life Calculations of Preloaded Angular Contact Ball Bearings

To establish the total radial ( $F_r$ ) and axial ( $F_a$ ) load components on each bearing in a multiple arrangement of preloaded angular contact ball bearings, the externally applied radial load ( $F_{re}$ ) and axial load ( $F_{ae}$ ), the axial preload ( $F_{ao}$ ) and the load distribution must be taken into account. The latter is a function of the rolling element to raceway deflection which is proportional to (load)<sup>2/3</sup>. The calculation procedure for popular mounting variations of identical bearings is detailed below.

Back-to-back, Pair of Bearings

Under external radial load ( $F_{re}$ ), total Preload ( $F_{ap}$ ) is the following:

$$F_{ap} = \frac{F_{re} \times 1.2 \times \tan \alpha + F_{ao}}{2}$$

when  $F_{ap} < F_{ao}$ , use  $F_{ap} = F_{ao}$

Total axial component of ( $F_{a1}, F_{a2}$ ) with applied axial load on each bearing (1 and 2):

$$F_{a1} = 2/3 F_{ae} + F_{ap}$$
$$F_{a2} = F_{ap} - 1/3 F_{ae}$$

when  $F_{a2} < 0$  the preload is relieved so that  $F_{a1} = F_{ao}$ , and  $F_{a2} = 0$

Total radial component of load ( $F_r$ ) on each bearing is proportioned by the ratio of the axial load on each bearing to the total axial load, each component raised to the power of 2/3:

$$F_{r1} = \frac{F_{a1}^{2/3}}{F_{a1}^{2/3} + F_{a2}^{2/3}} \times F_{re}$$
$$F_{r2} = \frac{F_{a2}^{2/3}}{F_{a1}^{2/3} + F_{a2}^{2/3}} \times F_{re}$$

The dynamic equivalent radial load ( $P_{r1}$ ) and ( $P_{r2}$ ) for each bearing is calculated from:

$$P_{r1} = XF_{r1} + YF_{a1}$$
$$P_{r2} = XF_{r2} + YF_{a2}$$

The values of X and Y are obtained from Table 1.1 (Page 139)

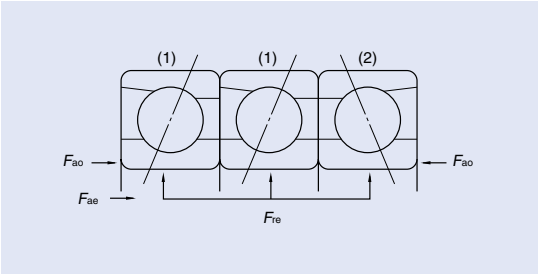

The basic rating life ( $L_{10}$ ) of each bearing is:

$$L_{10(1)} = \frac{16\,667}{n} \left( \frac{C_r}{P_{r1}} \right)^3 \quad (h)$$
$$L_{10(2)} = \frac{16\,667}{n} \left( \frac{C_r}{P_{r2}} \right)^3 \quad (h)$$

The two bearings may be considered as a unit and according to the theory of probability, the life of the unit, or pair of bearings, will be shorter than the shortest rating life of the individual bearings. Thus:

$$L_{10} = \frac{1}{\left( \frac{1}{L_{10(1)}^{1.1}} + \frac{1}{L_{10(2)}^{1.1}} \right)^{1/1.1}} \quad (h)$$

DBD Set of Bearings

Under external radial load ( $F_{re}$ ), total Preload ( $F_{ap}$ ) is the following:

$$F_{ap1} = \frac{F_{re} \times 1.2 \times \tan \alpha + F_{ao}}{4}$$
$$F_{ap2} = \frac{F_{re} \times 1.2 \times \tan \alpha + F_{ao}}{2}$$

when  $F_{ap1} < F_{ao}/2$ , use  $F_{ap1} = F_{ao}/2$

and  $F_{ap2} < F_{ao}$ , use  $F_{ap2} = F_{ao}$

Total axial component of load ( $F_{a1}, F_{a2}$ ) on each bearing with applied axial load :

$$F_{a1} = 0.4 F_{ae} + F_{ap1}$$
$$F_{a2} = F_{ap2} - 0.2 F_{ae}$$

When  $F_{a2} < 0$  the preload is relieved so that

$$F_{a1} = \frac{F_{ae}}{2} \text{ and } F_{a2} = 0$$

Total radial component of load ( $F_r$ ) on each bearing :

$$F_{r1} = \frac{F_{a1}^{2/3}}{2F_{a1}^{2/3} + F_{a2}^{2/3}} \times F_{re}$$
$$F_{r2} = \frac{F_{a2}^{2/3}}{2F_{a1}^{2/3} + F_{a2}^{2/3}} \times F_{re}$$

The dynamic equivalent radial load ( $P_{r1}$ ) and ( $P_{r2}$ ) for each bearing :

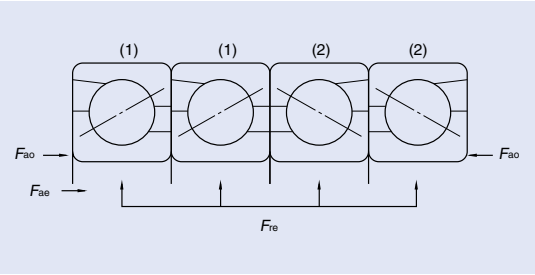

$$P_{r1} = XF_{r1} + YF_{a1}$$
$$P_{r2} = XF_{r2} + YF_{a2}$$

The values of X and Y are obtained from Table 1.1, page 139. The basic rating life ( $L_{10}$ ) of each bearing :

$$L_{10(1)} = \frac{16\,667}{n} \left( \frac{C_r}{P_{r1}} \right)^3 \quad (h)$$
$$L_{10(2)} = \frac{16\,667}{n} \left( \frac{C_r}{P_{r2}} \right)^3 \quad (h)$$

$$L_{10} \text{ for the unit} = \frac{1}{\left( \frac{1}{L_{10(1)}^{1.1}} + \frac{1}{L_{10(2)}^{1.1}} \right)^{1/1.1}} \quad (h)$$

DBB Set of Bearings

Under external radial load ( $F_{re}$ ), total Preload ( $F_{ap}$ ) is the following:

$$F_{ap} = \frac{F_{re} \times 1.2 \times \tan \alpha + F_{ao}}{4}$$

When  $F_{ap} < F_{ao}/2$ , use  $F_{ap} = F_{ao}/2$

Total axial component of load ( $F_{a1}, F_{a2}$ ) on each bearing with applied axial load

$$F_{a1} = 1/3 F_{ae} + F_{ap}$$
$$F_{a2} = F_{ap} - 1/6 F_{ae}$$

When  $F_{a2} < 0$  the preload is relieved so that

$$F_{a1} = \frac{F_{ae}}{2} \text{ and } F_{a2} = 0$$

Total radial component of load ( $F_r$ ) on each bearing :

$$F_{r1} = \frac{F_{a1}^{2/3}}{F_{a1}^{2/3} + F_{a2}^{2/3}} \times \frac{F_{re}}{2}$$
$$F_{r2} = \frac{F_{a2}^{2/3}}{F_{a1}^{2/3} + F_{a2}^{2/3}} \times \frac{F_{re}}{2}$$

The dynamic equivalent radial load ( $P_{r1}$ ) and ( $P_{r2}$ ) for each bearing :

$$P_{r1} = XF_{r1} + YF_{a1}$$
$$P_{r2} = XF_{r2} + YF_{a2}$$

The values of X and Y are obtained from Table 1.1, page 139. The basic rating life ( $L_{10}$ ) of each bearing :

$$L_{10(1)} = \frac{16\,667}{n} \left( \frac{C_r}{P_{r1}} \right)^3 \quad (h)$$
$$L_{10(2)} = \frac{16\,667}{n} \left( \frac{C_r}{P_{r2}} \right)^3 \quad (h)$$

$$L_{10} \text{ for the unit} = \frac{1}{\left( \frac{1}{L_{10(1)}^{1.1}} + \frac{1}{L_{10(2)}^{1.1}} \right)^{1/1.1}} \quad (h)$$

New Life Theory

Introduction

Bearing technology has advanced rapidly in recent years, particularly in the areas of dimensional accuracy and material cleanliness. As a result, bearings can now have a longer rolling fatigue life in a cleaner environment, than the life obtained by the traditional ISO life calculation formula. This extended life is partly due to the important advancements in bearing related technology such as lubrication cleanliness and filtration.

The conventional life calculation formula, based on the theories of G. Lundberg and A. Palmgren (L-P theory, hereafter) addresses only sub-surface originated flaking. This is the phenomenon in which cracks initially occur due to dynamic shear stress immediately below the rolling surface then progressively reach the surface in the form of flaking.

$$1n\frac{1}{S} \propto \frac{\tau_o^e \cdot N^e \cdot V}{Z_o^h}$$

NSK's new life calculation formula theorizes that rolling fatigue life is the sum total of the combined effects of both sub-surface originated flaking and surface originated flaking occurring simultaneously.

NSK New Life Calculation Formula

(1) Sub-surface originated flaking

A pre-condition of sub-surface originated flaking of rolling bearings is contact of the rolling elements with the raceway via a sufficient and continuous oil film under clean lubrication conditions.

Fig. 1.1 plots the  $L_{10}$  life for each test condition with maximum surface contact pressure ( $P_{max}$ ) and the number of repeated stresses applied on the ordinate and the abscissa, respectively.

In the figure, line  $L_{10}$  theoretical is the theoretical line obtained using the conventional life calculation formula. As maximum surface contact pressure decreases, the actual life line separates from the line created by using conventional theoretical calculation and moves towards longer life. This separation suggests the presence of fatigue load limit  $P_u$  below which no rolling fatigue occurs. This is better illustrated in Fig. 1.2.

Fig. 1.1 Life Test Result under Clean Lubrication Condition

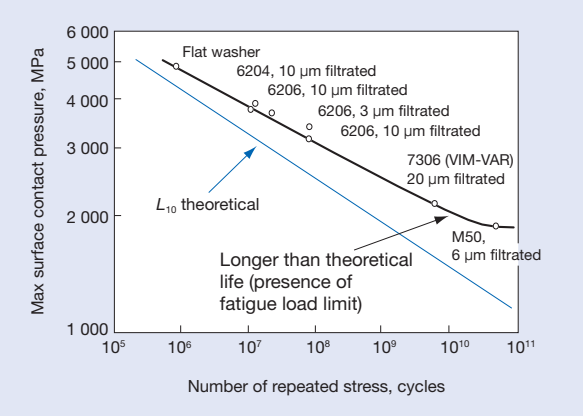

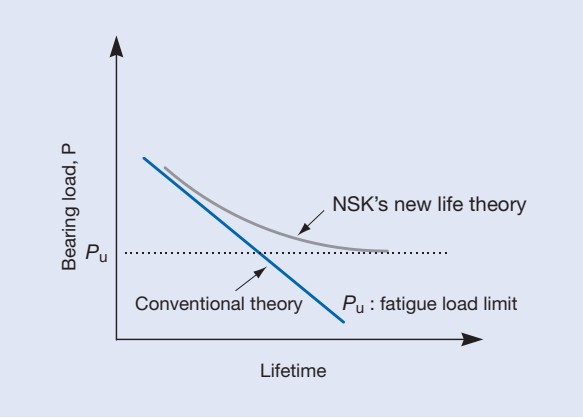

Fig. 1.2 NSK's New Life Theory That Considers Fatigue Limit

(2) Surface originated flaking

Under actual bearing operation, the lubricant is often contaminated with foreign objects such as metal chips, burrs, cast sand, etc.

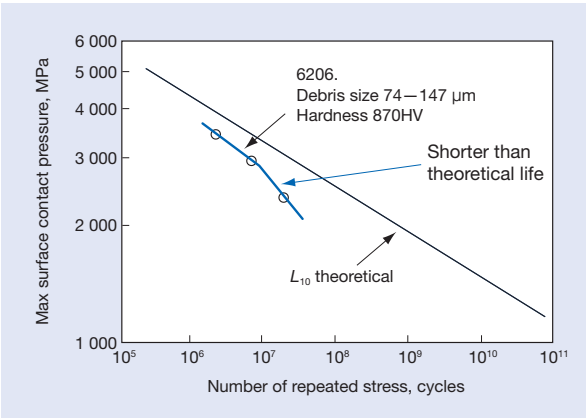

When the foreign particles are mixed in the lubricant, the particles are pressed onto the raceways by the rolling elements and dents occur on the surfaces of the raceways and rolling elements. Stress concentration occurs at the edges of the dents, generating fine cracks, which over time, propagate into flaking of the raceways and rolling elements.

As shown in Fig. 1.3, the actual life is shorter than conventional calculated life, under conditions of contaminated lubrication at low max surface pressure. The actual life line separates from the line created by theoretical life calculations and moves towards a shorter life. This result shows that the actual life under contaminated lubrication is further shortened compared to the theoretical life because of the decrease in maximum surface contact pressure.

Table 1.3 Value of Contamination Coefficient  $a_c$

	Very clean	Clean	Normal	Contaminated	Heavily contaminated
$a_c$ factor	1	0.8	0.5	0.4–0.1	0.05
Application guide	10 μm filtration	10–30 μm filtration	30–100 μm filtration	Greater than 100 μm filtration or no filtration (oil bath, circulating lubrication, etc.)	No filtration, presence of many fine particles
Application examples	Sealed grease lubricated bearing for electrical appliances and information technology equipment, etc.	Sealed grease lubricated bearing for electric motors Sealed grease bearing for railway axle boxes and machine tools, etc.	Normal usage Automotive hub unit bearing, etc.	Bearing for automotive transmission; Bearing for industrial gearbox; Bearing for construction machine, etc.	—

Fig. 1.3 Life Test Result under Contaminated Lubrication Condition

Therefore, the NSK new life calculation formula considers the trend in the results of the life test under conditions of clean environment and at low load zone. Based on these results, the new life equation is a function of  $(P-P_u)/C$ , which is affected by specific lubrication conditions identified by the lubrication parameter. Also, it is assumed that effects of different types and shapes of foreign particles are strongly influenced by the bearing load and lubrication conditions present, and that such a relationship can be expressed as a function of the load parameter. This relationship of the new life calculation formula is defined by  $(P-P_u)/C \cdot 1/a_c$ .

Calculation formula for surface originated flaking, based on the above concept, is as follows:

$$1n\frac{1}{S} \propto N^e \int_v \frac{(\tau - \tau_u)^e}{Z_o^h} dV \times \left\{ \frac{1}{f(a_c, a_L)} - 1 \right\}$$

$V$  = stress volume

The contamination coefficient in terms of lubrication cleanliness is shown in Table 1.3. Test results on ball and roller bearings with grease lubrication and clean filtration show the life as being a number of times longer than that of the contaminated calculation. Yet when the foreign object is harder than Hv350, hardness becomes a factor and a dent appears on the raceway. Fatigue damage from these dents, can progress to flaking in a short time. Test results on ball and roller bearings under conditions of foreign object contamination show from 1/3 to 1/10 the life when compared with conventionally calculated life.

Based on these test results, the contamination coefficient  $a_c$  is classified into five steps for NSK's new life theory.

(3) New life calculation formula

The following formula, which combines sub-surface originated flaking and surface originated flaking, is proposed as the new life calculation formula.

$$1n\frac{1}{S} \propto N^e \int_v \frac{(\tau - \tau_u)^e}{Z_o^h} dV \times \left\{ \frac{1}{f(a_c, a_L)} \right\}$$

$$L_{\text{able}} = a_1 \cdot a_{\text{NSK}} \cdot L_{10}$$

Life Correction Factor  $a_{NSK}$

The life correction factor  $a_{NSK}$  is the function of lubrication parameter  $(P-P_u)/C \cdot 1/a_c$  as shown below:

$$a_{NSK} \propto F \left\{ a_L, \left( \frac{P-P_u}{C \cdot a_c} \right) \right\}$$

NSK's new life theory considers the life extending affect of improved material and heat treatment by correcting the contamination factor  $a_c$ . The theory also utilizes viscosity ratio  $k$  ( $k = \nu/\nu_1$  where  $\nu$  is the operational viscosity and  $\nu_1$  the required viscosity) because the lubrication parameter  $a_L$  changes with the degree of oil film formation, based on the lubricant and operating temperature. The theory indicates that the better the lubrication conditions (higher  $k$ ) the longer the life.

Figures 1.4 and 1.5 show the diagrams of the correction factor  $a_{NSK}$  as a function of the new life calculation formula. Also in this new life calculation formula, point contact and line contact are considered separately for ball and roller bearings respectively.

New Life Calculation Formula  $L_{able}$

The concept of new life calculation formula is simplified into one factor as shown by the formula below in which conventional life calculation formula ( $L_{10}$ ) is multiplied with correction factor ( $a_{NSK}$ ) and reliability factor ( $a_1$ ; Table 1.4):

$$L_{able} = a_1 \cdot a_{NSK} \cdot L_{10}$$

Table 1.4 Reliability Factor

Life of High Speed Bearings

When bearings operate at high speed, in addition to the external load, the internal load generated by the centrifugal force acting on the rolling element must be taken into account. A computer should be used for the calculation of the load conditions on bearings operation at high speeds (in excess of 800 000  $d_m n$ ). Balance among the forces acting on the rolling elements and inner/outer rings as well as changes in contact angle are obtained by using convergence calculations<sup>(1)</sup>, based on the load condition of the bearing (radial load, axial load, centrifugal force on rolling elements, etc.).

Life is initially calculated for each individual rolling element under load between inner and outer ring and then the life of the entire single row of bearing is obtained.

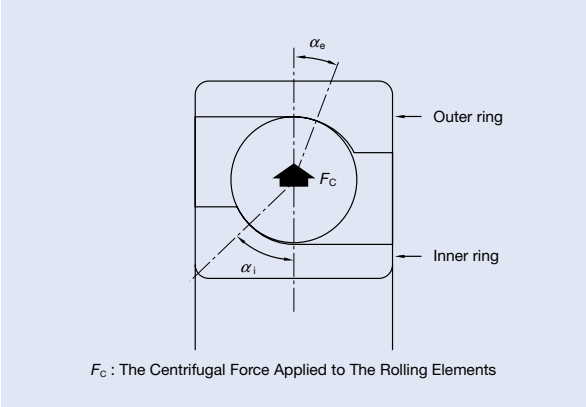

<sup>(1)</sup> Convergence calculations allow NSK to calculate with great accuracy the centrifugal force exerted on balls and to actually perform load calculations for each rolling element.

For life calculations on bearings used in high speed applications, please contact NSK.

Life of Ceramic Hybrid Bearings

$C_r$ ,  $C_{or}$  values and  $L_{10}$  standards do not exist in ISO281 for ceramic bearings. However, ceramic bearing life tends to be longer than that of conventional steel ball bearings, under the same appropriate operating conditions. This may be especially true in the situations where the centrifugal force on the balls are significant.

Fig. 1.6 Change in Contact Angle Due to Centrifugal Force

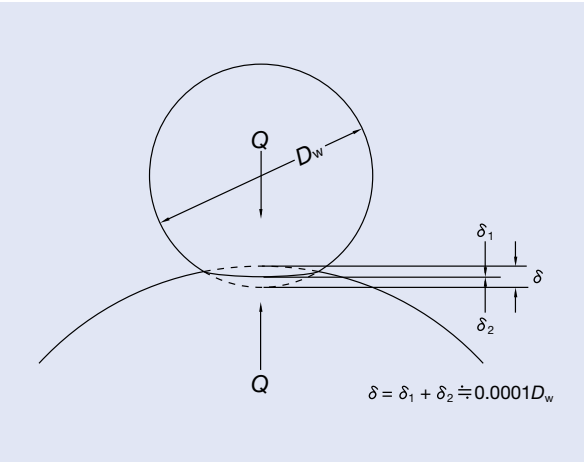

Static Load Ratings

When subjected to an excessive load or a strong shock load, rolling bearings may incur a local permanent deformation of the rolling elements and raceway surface if the elastic limit is exceeded. The nonelastic deformation increases in area and depth as the load increases, and when the load exceeds a certain limit, the smooth running of the bearing is impeded. The basic static load rating is defined as that static load which produces the following calculated contact stress at the center of the contact area between the rolling element subjected to the maximum stress and the raceway surface.

For ball bearings : 4 200MPa  
For roller bearings : 4 000MPa

In this most heavily contacted area, the sum of the permanent deformation of the rolling element and that of the raceway is nearly 0.0001 times the rolling element’s diameter. The basic static load rating  $C_0$  is written  $C_{0r}$  for radial bearings and  $C_{0a}$  for thrust bearings in the bearing tables.

Fig. 2.1 The Relation between Indentations and Basic Static Load Rating

Static Equivalent Loads

The static equivalent load is a hypothetical load that produces a contact stress equal the maximum stress under actual conditions, while the bearing is stationary (including very slow rotation or oscillation), in the area of contact between the most heavily stressed rolling element and bearing raceway. The static radial load passing through the bearing center is taken as the static equivalent load for radial bearings, while the static axial load in the direction coinciding with the central axis is taken as the static equivalent load for thrust bearings. Static equivalent load on radial bearings. The greater of the two values calculated from the following equations should be adopted as the static equivalent load on radial bearings.

$$P_0 = X_0 F_r + Y_0 F_a$$
$$P_0 = F_r$$

Static equivalent load on thrust bearings:

$$P_0 = X_0 F_r + F_a \quad \alpha \neq 90^\circ$$

Table 2.1 Static Equivalent Load  $P_0 = X_0 F_r + Y_0 F_a$

Contact Angle	Single DT		DB or DF		where
	$X_0$	$Y_0$	$X_0$	$Y_0$	
15	0.5	0.46	1	0.92	$P_0$ : Static equivalent load (N)
18	0.5	0.42	1	0.84	$F_r$ : Radial load (N)
25	0.5	0.38	1	0.76	$F_a$ : Axial load (N)
30	0.5	0.33	1	0.66	$X_0$ : Static radial load factor
40	0.5	0.26	1	0.52	$Y_0$ : Static axial load factor

When single or DT mounting and  $F_r > 0.5F_r + Y_0F_a$ , use  $P_0 = F_r$

Permissible Static Load Factor

The permissible static equivalent load on bearings varies depending on the basic static load rating and also their application and operating conditions. The permissible static load factor is a safety factor that is applied to the basic static load rating, and it is defined by the ratio in equation below:

$$f_s = (C_0 / P_0)$$

where

$C_0$  : Basic static load rating (N)  
 $P_0$  : Static equivalent load (N)

Table 2.2 Values of Permissible Static Load Factor  $f_s$

Operating conditions	Lower limit of $f_s$	
	Ball bearings	Roller bearings
Low-noise applications	2.0	3.0
Bearings subjected to vibration and shock loads	1.5	2.0
Standard operating conditions	1.0	1.5

Permissible Axial Loads

In order to optimize bearing performance, NSK has defined the permissible axial loads statistically, based on the following 2 situations:

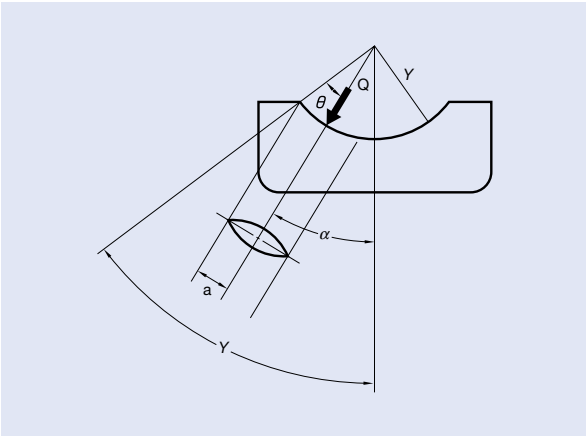

- The limiting load at which a contact ellipse is generated between the ball and raceway due to a change in the contact angle when a radial bearing, which is under an axial load, rides over the shoulder of the raceway groove.
- The value of a static equivalent load  $P_0$  which is determined from the basic static load rating  $C_0$  using static axial load factor  $Y_0$ .

The permissible axial load is determined by the lower of the two values defined above.

This value has been proven through experience, and includes a safety factor.

(Refer to the bearing tables for permissible axial loads)

Fig. 2.2 Contact Ellipse and the Limiting Axial Loads

Angular Contact Ball Bearing Combinations Available

Normally, NSK supplies matched super precision angular contact ball bearings as 2, 3, and 4 row combinations. The combinations available for the fixed end of spindles are usually 2 rows (DB), 3 rows (DBD), and 4 rows (DBB) sets. However, in the case of 3 row combinations, since the preload distribution to each bearing is not equal, the optimum preload setting range is very limited, making them unsuitable for high speed applications. Matched bearings are manufactured as sets, so when they are mounted adjacent to each other, a given preload is automatically obtained. The variation per pair of matched bearings for bore and outer diameters is adjusted to less than 1/3 of the permissible tolerance.

Table 3.1 Features of Each Combination

	DB	DF	DT	DBD	DBB
Load direction	↔	↔	→	↔	↔
Moment stiffness	◎	○	△	◎	◎
Speed capability	◎	◎	◎	△	○
Heat generation	◎	◎	◎	△	○
Stiffness	○	○	△	◎	◎

◎Excellent ◎Very good ○Good △Fair →One direction only ↔Two directions

Features of Each Combination

- Back-to-back Arrangement, DB  
Axial loads in both directions and radial loads can be sustained. Since the distance between the effective load centers is large, this type is suitable if moments are applied. However, if accuracy of housing is not enough and there is a misalignment in the spindle, internal loads of bearings could be large enough to possibly cause premature failure due to greater moment stiffness.
- Face-to-face Arrangement, DF  
Compared with the DB type, the distance between the effective load centers is small, so the capacity to sustain moments is inferior to the DB type. On the other hand, this type is suitable for using with housings that have less accuracy or larger shaft deflections due to low bending stiffness of shaft.
- Tandem Arrangement, DT  
Axial loads in one direction and radial loads can be sustained. Since axial stiffness of this type is twice the value of a single row type, this arrangement is used when the axial load in one direction is heavy.
- 3 rows Arrangement, DBD  
Axial loads in both directions and radial loads can be sustained. However, the preload distribution to each bearing is not equal, and preload on the counter side (single side) is twice that of other side. Consequently, this type is unsuitable for high speed operation because of the large increase of internal load of the single side which could lead to bearing failure.
- 4 rows Arrangement, DBB  
Axial loads in both directions and radial loads can be sustained. In situations that have the same axial clearance as DB arrangement, preload and stiffness are twice that of the DB arrangement. Also, the permissible axial load of a 4 row arrangement is larger than that of a DB arrangement.

Fig. 3.1 The Distance between the Effective Load Centers of Back-to-back and Face-to-face Arrangements

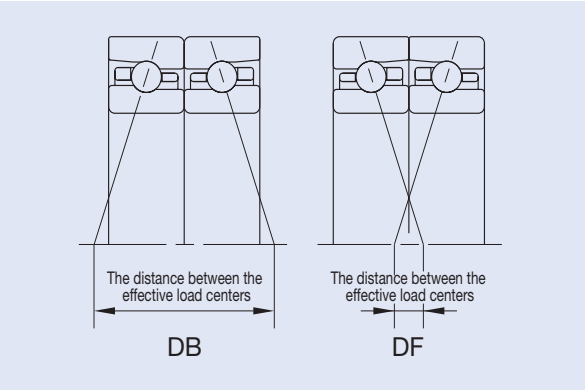

Fig. 3.2 Load Direction in Back-to-Back and Tandem Arrangements

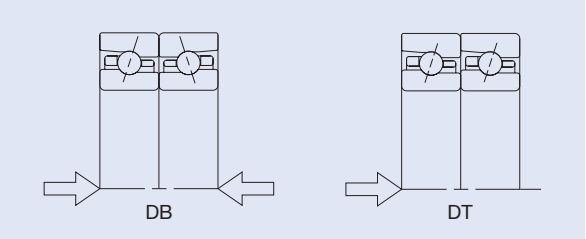

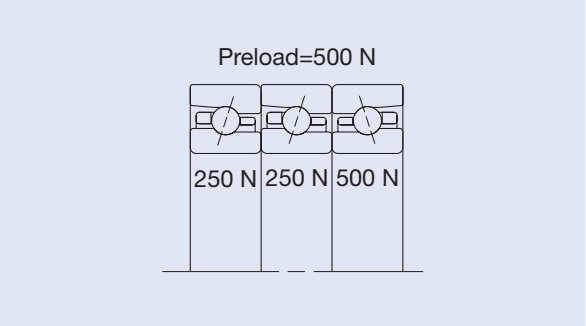

Fig. 3.3 Internal Preload in DBD Arrangement

Shaft Bending Comparison between Back-to-back and Face-to-face Arrangements

Moment stiffness is different between Back-to-back and Face-to-face arrangements as shown in the shaft bending comparison calculation example below. In this example, angular contact ball bearings (75BNR10XET) are used in the front side and the typical shaft deflections are shown for both DB and DF configurations. When 1 000 N of radial load is applied on the spindle nose, radial displacements on the spindle nose are calculated as follows.

$\sigma_{DB} = 2.4079 \times 10^{-2}$   
 $\sigma_{DF} = 2.9853 \times 10^{-2}$

This demonstrates the effect of the distance between effective load centers on spindle bending.

Mounting Instructions for Angular Contact Ball Bearings — Matching Method

Direction of Matching

For matched bearings, the mounting order and load application direction are very important. A “V” is marked on the outer diameter surfaces of the bearings as shown in the figure on the right. When the bearings are mounted so their marks correctly form a “V”, they are properly matched and aligned. On the side surface or chamfered part of the inner rings, the symbol “○” is marked to indicate the position of maximum radial runout. Optimum accuracy is achieved when the bearing is mounted so the “○” symbol is placed just opposite the position of shaft maximum eccentricity.

Fig. 3.5 The Symbol for the Position of Maximum Radial Runout of Inner Ring

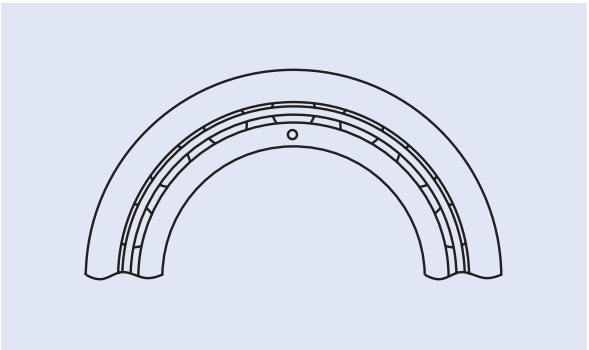

Fig. 3.4 Spindle Displacement Curve

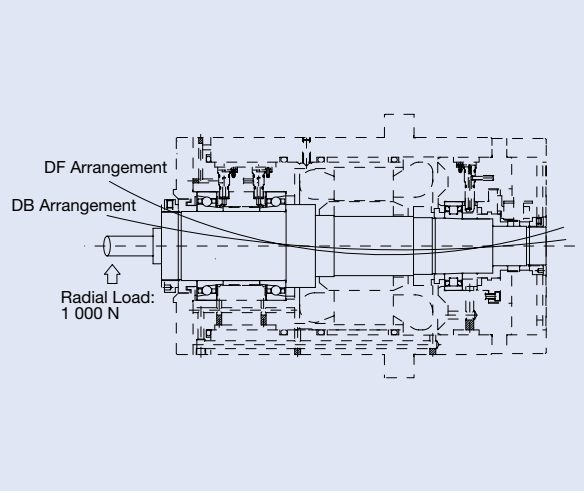

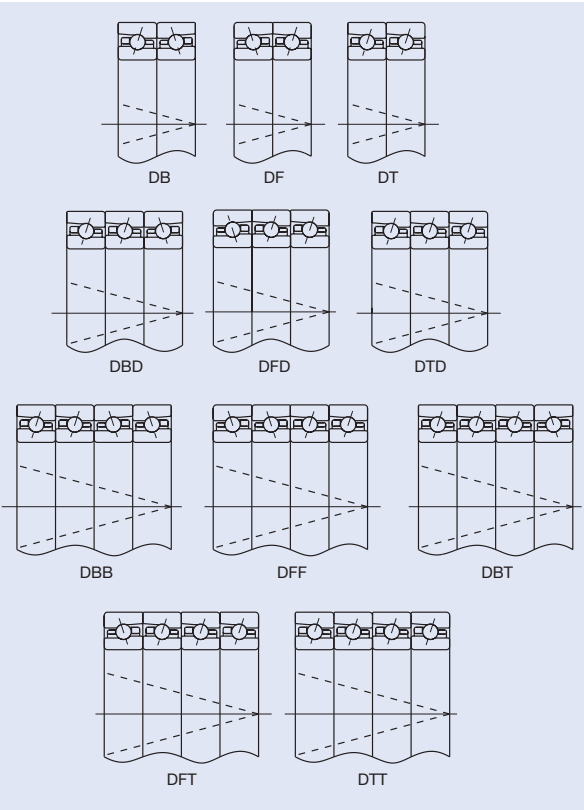

Fig. 3.6 Combinations of Angular Contact Ball Bearings

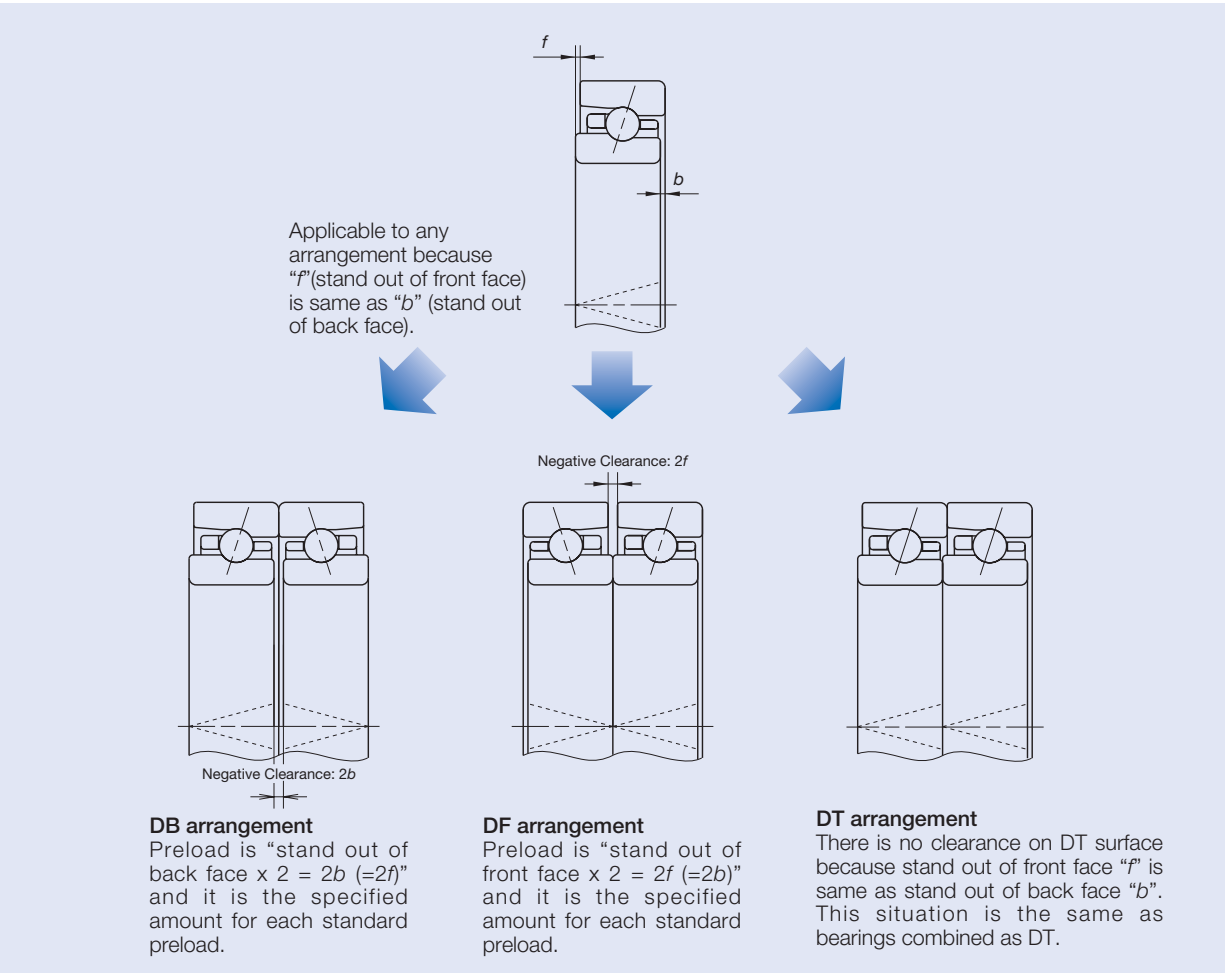

Universal Combination

NSK supplies universal combination angular contact ball bearings that have the same amount of stand out on both the front and back face. This means that when bearings that have the same reference number are combined, they have the specified amount for each standard preload.

For universal combination bearings, the “V” combination marks on the outer diameter surface of outer ring prevent “direction” mistakes, ensure correct matching when they are mounted, and indicate the direction of the contact angle.

Fig. 3.7 Universal Combination

Difference between SU and DU Bearings

There are 2 types of NSK universal combination bearings as shown in the table below.

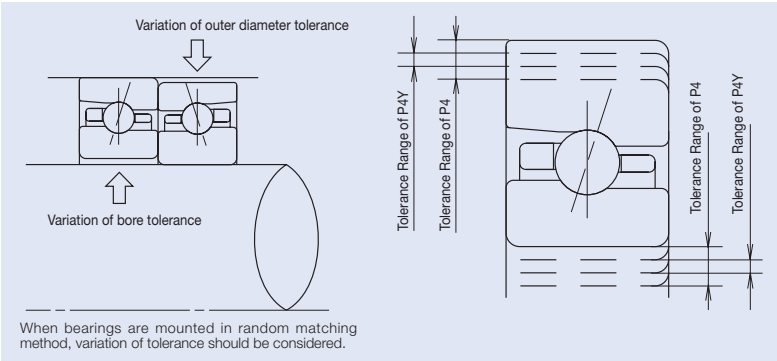

Table 3.2 Features of SU and DU Bearings

	SU	DU
Row of bearings	1	2
Variation of bore and outer diameter tolerance	—	Controlled in 1/3 of tolerance

Notice for Use of Single Universal (SU) Bearings

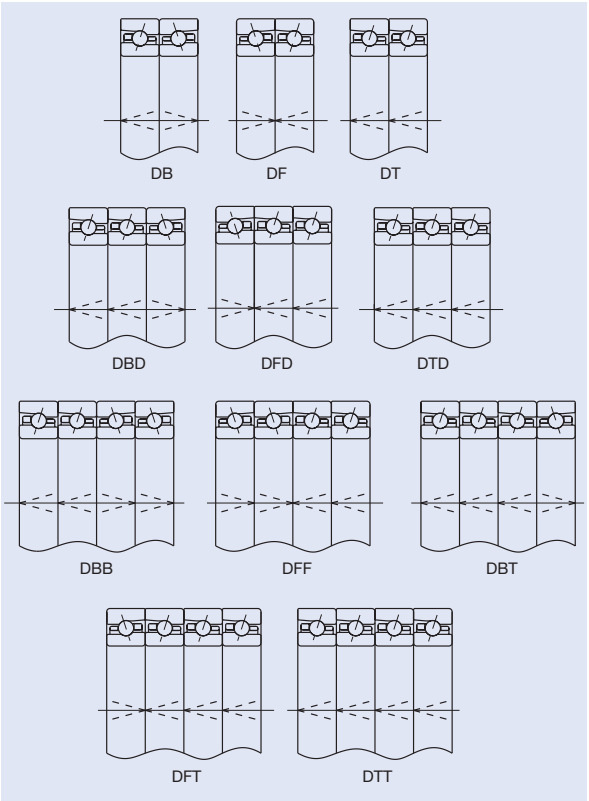

- When these bearings are used as part of multiple combined bearings, it is recommended that the variation of bore and outer diameter tolerance is within 1/3 of tolerance range.
- There are also special bearings with special accuracy “Class 4Y” that can accommodate small variations of bore and outer diameter tolerance. “Class 4Y” tolerance has the same running accuracy as Class 4 but has a narrower tolerance range of bore and outer diameter than Class 4. It is suitable for “random matching method” universal combination bearings.
- “Class 4Y” is suitable for use “random matching method” universal combination bearings. However, when these bearings are operated over 1 500 000  $d_m n$ , there is a possibility that this very small variation of fits with either the shaft or the housing can cause bearing failure because of imbalance of internal load in each row. If these bearings are considered for such high speed applications, this issue should be taken into account.

200	Under 215	0	−11	−2	−9

\*Tolerances for bearings under 50 mm outer diameter are the same as values quoted between 50–80 mm outer diameter.

Regarding the rigidity of machine tool spindles, it is possible to think of the bearings as being springs. Axial displacement, when an axial load is applied to the spindle, is determined by the axial rigidity of the fixed end bearings.

When high radial rigidity is required, cylindrical roller bearings are generally used. Axial loads are usually sustained by angular contact ball bearings. The bigger the contact angle of the angular contact ball bearings, the higher the axial rigidity. Bearings of the same bore size, which have more rolling elements (diameter series 0 or 9; or BNR10 or BNR19 series), have higher rigidity, even though the diameter or the rolling elements is smaller.

Normally, preload is applied to bearings in order to increase rigidity of machine tool spindles. But if the preload is excessively high, flaking and possible seizure will result. Many users increase rigidity by using a combination of two or more angular contact ball bearings. This is especially true for ball screw support bearings, where high rigidity is required, the contact angle is big, and preload is higher than that for a spindle. Axial loads are widely sustained with two or three bearings.

Purpose

The main purposes of preloaded bearings in a machine tool spindle are as follows:

- To improve and maintain the running accuracy of the shaft.
- To increase bearing rigidity.
- To minimize noise due to axial vibration and resonance.
- To prevent false brinelling.
- To prevent sliding between the rolling elements and raceways due to gyroscopic moments.
- To maintain the rolling elements in their proper position.

Usually a preload is applied to bearings by using two or more bearings in combination with each other, such as angular contact ball bearings or tapered roller bearings.

Cylindrical roller bearings can be preloaded by making the radial internal clearance negative.

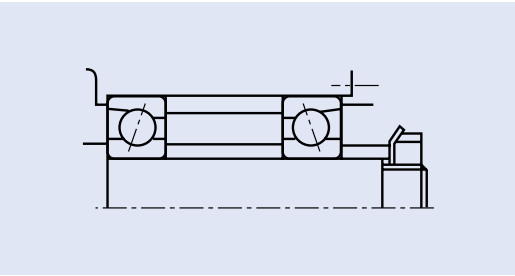

(1) Position Preload

A position preload is achieved by fixing two axially opposed bearings in a position that remains unchanged while in operation. In practice, the following three methods are generally used to obtain a position preload.

1. By installing a duplex bearing set with previously adjusted stand-out dimensions and axial clearance
2. By using a spacer or shim of proper size to obtain the required spacing and preload (see Fig. 4.1).
3. By utilizing bolts or nuts to allow adjustment of the axial preload (In this case, the starting torque should be measured to verify the proper preload. However, this method cannot be recommended for high precision machine tool spindles due to difficulty in verifying the proper

preload, thus risking vertical displacement (tilting) of the bearing.)

Fig. 4.1 Position Preload

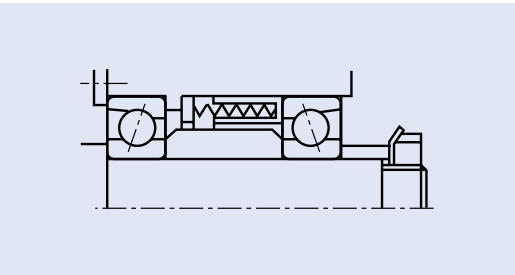

(2) Constant Pressure Preload

A constant pressure preload is achieved using a coil or leaf spring.

Even if the relative position of the bearings change during operation, the magnitude of the preload remains relatively constant. An angular contact ball bearing arrangement for high speed rotation is shown in Fig. 4.2.

Fig. 4.2 Constant Pressure Preload

Change of Rigidity by Preload

Position Preload and Axial Rigidity

When the inner rings of the duplex bearings shown in Fig. 4.3 are fixed axially, bearings A and B are displaced  $\delta_{aoA}$  and  $\delta_{aoB}$  and axial space  $\delta_{ao}$  between the inner rings is eliminated. With this condition, a preload  $F_{ao}$  is imposed on each bearing. The relation between axial load,  $F_a$  and displacement in a duplex set is shown in Fig. 4.4. Figures 4.5 and 4.6 illustrate the same concepts for a DBD arrangement.

Back-to-Back Arrangement (DB)

Fig. 4.3 Preloaded DB Arrangement

- $\delta_{aB}$  : Displacement of Bearing B

Constant Pressure Preload and Axial Rigidity

Fig. 4.7 illustrates duplex bearing under constant pressure preload. The deflection curve of the spring is nearly parallel to the horizontal axis due to the rigidity of the springs being smaller than that of the bearing. As a result, rigidity under constant pressure preload is approximately equal to that for a single bearing with a preload of  $F_{a0}$  being applied to it. Fig. 4.8 compares the rigidity of a bearing with position preloading and one with constant pressure preloading.

Fig. 4.7 Axial Displacement with Constant Pressure Preload

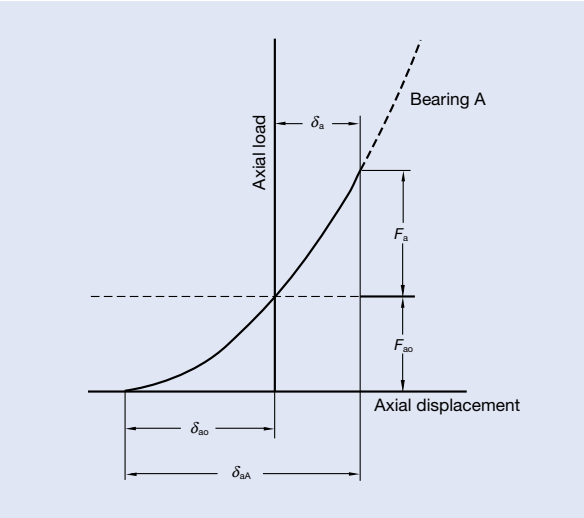

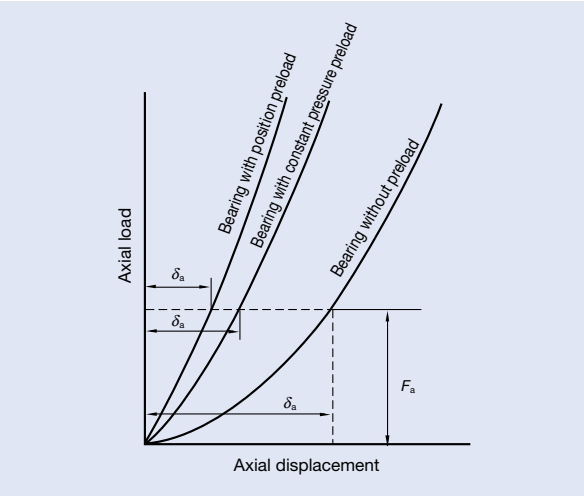

Fig. 4.8 Comparison of Stiffness and Preloading

Comparison of Preloading Methods

Position preload and constant pressure preload can be compared as follows:

- (1) When both of the preloads are equal, the position preload provides greater bearing rigidity. In other words, the deflection due to external loads is less for bearings with a position preload.
- (2) Under position preload, the preload varies depending on such factors as a difference in axial expansion due to a temperature difference between the shaft and housing, a difference in radial expansion due to a temperature difference between the inner and outer rings, and deflection due to load. Under constant pressure preload, it is possible to minimize any change in preload because the variation of the spring load with shaft expansion and contraction is negligible.

From the foregoing explanation, it is seen that position preloads are generally preferred for increasing rigidity while constant pressure preloads are more suitable for high speed applications.

Preload Amount

A larger preload results in higher rigidity. However, if preload is larger than necessary, abnormal heat is generated, which reduces fatigue life. In extreme cases, it may result in excessive wear or even seizure. Therefore, the amount of preload should be carefully studied and selected to avoid excessive preload while taking into consideration the type of application and the operating conditions.

High Speed Spindles and Preload

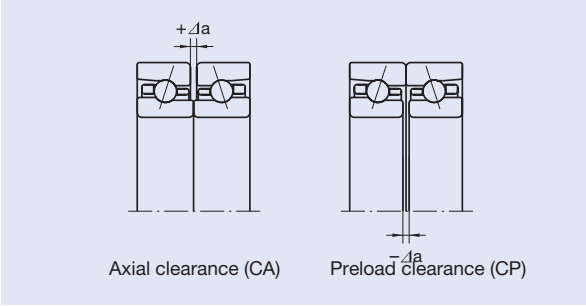

When bearings operate at high speed, the contact surface pressure between the balls and the inner and outer ring raceways increases due to expansion of the internal axial load caused by centrifugal force, generation of internal axial load caused by centrifugal force on the balls, and temperature difference between inner and outer rings. For bearings having a contact angle, such as angular contact ball bearings, pure rolling motion with sliding due to spin moments and gyroscopic moments on the balls may occur. Sliding increases as bearing speed increases. As a result, the intensity of heat generated in the contact areas increases and the viscosity of the lubricating oil decreases. In some cases, a breakdown of the oil film occurs, resulting in complete seizure of the bearing. In other words, if the contact surface pressure at low speed operation is equal to that of high speed operation, then heat generation, which is due to sliding at high speeds, becomes more intense. This concept can be expressed quantitatively as a  $Pv$  value, where  $P$  is the contact surface pressure, and  $v$  is the slip rate. The  $Pv$  value can be applied to the rolling contact area of the bearing. If the  $Pv$  value is constant, sliding is greater at high speed operation than at low speed operation. Whereas velocity is increased, it

becomes necessary to reduce the contact surface pressure. NSK can calculate contact surface pressure and slip rate generated during high speed operations by computer. Taking advantage of abundant empirical test data and actual market results, we can determine the preload according to limiting factors, which are based on the lubricating method and rotating speed. For operations exceeding 800 000  $d_m n$ , please contact NSK.

Special Clearance

For special clearance of combined angular contact ball bearings, NSK offers both CA and CP clearances. CA: axial clearance (Clearance exists in the axial direction) CP: preload clearance (Preload is generated)

Fig. 4.9 Special Clearance

Preload Adjustment

When you change preload (for example "EL→L"), please adjust the difference of the measured axial clearance, by a spacer. (When increasing preload, inner spacer should be shorter, and outer spacer should be shorter when decreasing preload) Please refer to Pages 156–166 of the measured axial clearances. Please refer the measuring load of axial clearance to Table 4.1.

Table 4.1 Measuring load of axial clearance

Nominal Outside Diameter (mm)		Measuring load (N)

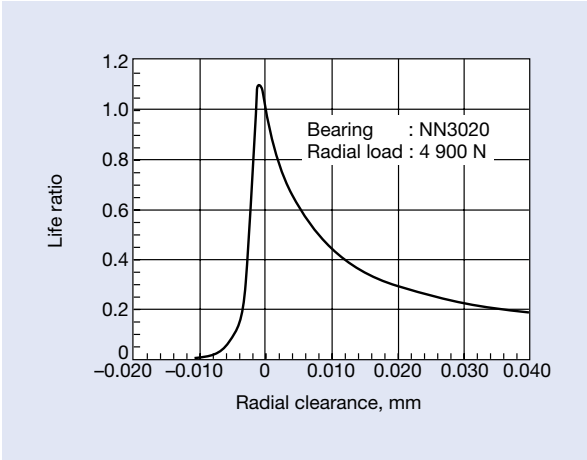

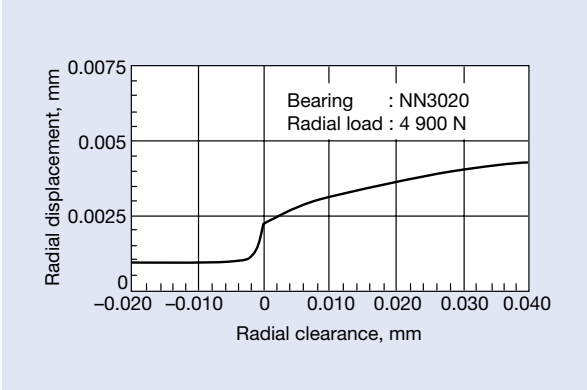

Fig. 4.11 Radial Clearance in Double Row Cylindrical Roller Bearing and Variation of Rigidity

Internal Clearance in Cylindrical Roller Bearings

In order for machine tool spindles to have high running accuracy and rigidity, bearings are used with minimum internal clearance or preload after mounted. Cylindrical roller bearings with tapered bores are usually used to allow easier adjustment of internal clearance. In general, cylindrical roller bearings for the front end (fixed end) of the spindle are adjusted to apply a preload during operating. Bearing for the rear end (free end) are adjusted when mounted to produce a slight clearance during operating. The amount of radial internal clearance after mounted is based on several factors such speed, load, lubricating method, bearing size, required rigidity, life, etc. Fig. 4.10 illustrates the relation between radial internal clearance in a bearing and life. Fig. 4.11 shows the relation between radial internal clearance and radial elastic displacement of an NN3020 (Bore diameter 100 mm, outside diameter 150 mm, width 37 mm).

156 | **NSK** \* When a ceramic ball is used, Preload and axial rigidity value will be 1.2 times the value of steel ball. The value in ( ) shows a measured axial clearance.

Calculation of radial rigidity  
Multiply axial rigidity by factors  
in table A.

Table A		EL	L	M	H
15°	6.5	6.0	5.0	4.5	
18°		4.5			
25°			2.0		
30°			1.4		
40°	0.7				

Calculation of preload and axial rigidity for combination bearings  
Multiply by factors in table B.  
For radial rigidity, multiply the value obtained in table A with factors in table B.

Table B		DBD	DBB
Preload factor		1.36	2
Axial rigidity		1.48	2
Radial rigidity		1.54	2

Calculation of radial rigidity  
Multiply axial rigidity by factors in table A.

Table A		EL	L	M	H
15°	6.5	6.0	5.0	4.5	
18°		4.5			
25°			2.0		
30°			1.4		
40°	0.7				

Calculation of preload and axial rigidity for combination bearings  
Preload and axial rigidity can be obtained by multiplying factors in table B.  
For radial rigidity, multiply the value obtained in table A with factors in table B.

Table B		DBD	DBB
Preload factor	1.36	2	
Axial rigidity	1.48	2	
Radial rigidity	1.54	2

The value in ( ) shows a measured axial clearance.

4. PRELOAD AND RIGIDITY

Preload and Rigidity (DB and DF Arrangement)

Ultra High Speed Angular Contact Ball Bearings

(ROBUST series)

Calculation of radial rigidity  
Multiply axial rigidity by factors  
in table A.

Table A

	EL	L	M	H
15°	6.5	6.0	5.0	4.5
18°	4.5			
25°	2.0			
30°	1.4			
40°	0.7			

Calculation of preload and axial  
rigidity for combination bearings  
Preload and axial rigidity can be  
obtained by multiplying factors in  
table B.  
For radial rigidity, multiply the value  
obtained in table A with factors in  
table B.

Table B

	DBD	DBB
Preload factor	1.36	2
Axial rigidity	1.48	2
Radial rigidity	1.54	2

<sup>(2)</sup> Denotes normal clearance for matched cylindrical roller bearings.

Limiting Speeds

The limiting speeds listed in the Bearing Dimensional Tables are guideline values. They are based on a single bearing that is lightly preloaded by means of a spring and subjected to relatively light loads with good heat dissipation.

The limiting speeds with grease lubrication are determined using high quality grease in appropriate amounts. Those listed for oil lubrication are based on the use of oil-air (or oil mist) lubrication. In situations where the lubricating oil is used as a means to remove heat, higher speed can be achieved, however a large amount of oil must be pressure fed through the bearing, so there is a significant loss of power.

When single bearings are used in two, three or four row combinations, or the preload is increased to improve spindle rigidity, limiting speeds will be lower than those listed.

Please consult NSK for grease lubrication, as grease life must be also taken into consideration.

Speed Factors

The limiting speed of a matched bearing set operating under position preload conditions is calculated by multiplying the limiting speed of a single bearing in the set by the appropriate adjustment factor listed in Table 5.1.

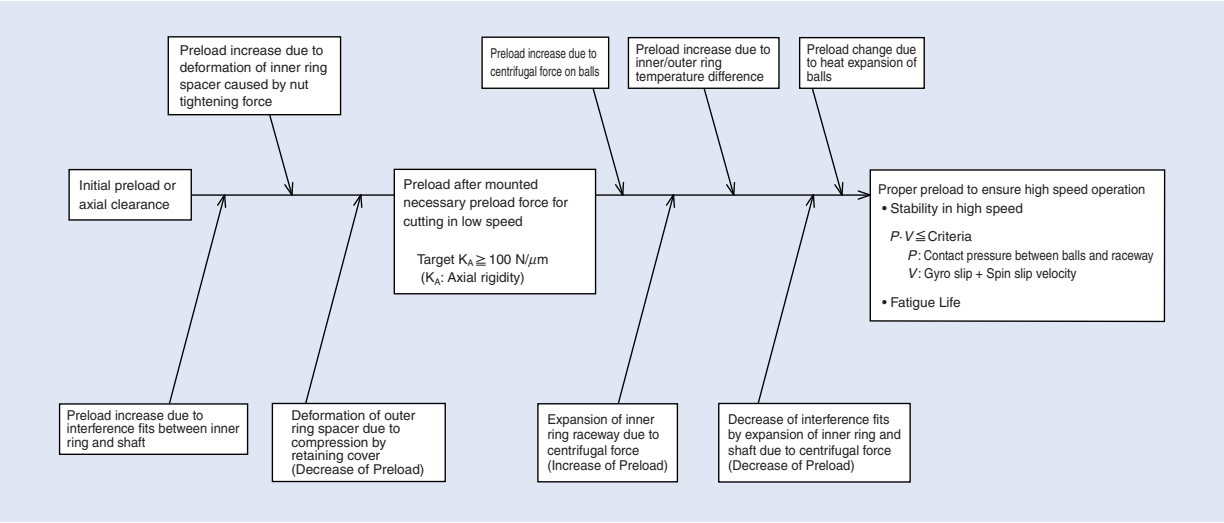

In this table, preloads mean the preload values after the bearing has been attached to the spindle. Preload values after the bearing has been mounted on the spindle will change as a result of the shaft fit requirements of high speed operation and spacer deformation due to tightening force. In such case, particular in high speed applications, it is necessary to adjust the spacer lengths relative to each other in order to compensate for the changes in preload after bearing mounting.

Table 5.1 Speed Factors

	Arrangement	EL	L	M	H
DB		0.85	0.80	0.65	0.55
DBB		0.80	0.75	0.60	0.45
DBD		0.75	0.70	0.55	0.40

Factors that Change Preload

Fig. 5.1 Preload Setting Study Flow

Factors Influencing Limiting Speeds

The limiting speed of the bearing, inside of the spindle, is affected by the following operating conditions.

1. Lubrication Method

The thickness of the lubricating film created by the oil-air or oil mist lubrication replenishment method is larger compared to the thickness created by the grease lubrication method. Therefore the limiting speed is higher when the oil-air or oil mist lubrication method is used.

In the case of jet lubrication, the large volume of oil supplied into the bearing for lubrication also removes heat efficiently so that much higher operating speeds are possible.

2. Combination

If bearings are used as multiple bearing sets, the number of bearings in the set affects the limiting speed. As the number is increased, the limiting speed becomes lower because the ability to dissipate that heat becomes lower.

3. Preload

If the preload after mounted is high, the contact surface pressure between the rolling elements and raceways increases, which causes extra heat. As a result of this heat, the preload during operation increases further and the risk of bearing failure will be higher. To avoid this type of bearing failure, the limiting speed is reduced. Also in case of cylindrical roller bearings, when the radial clearance is reduced and the preload increases during operation, the limiting speed is reduced.

4. Drive Method

The limiting speed of a bearing will also change depending on the spindle drive system.

In the case of motor built-in spindles the heat inside of the spindles is higher. If there is also a jacket-cooling system, the temperature difference between the inner ring and the outer ring becomes higher, so the preload is increased and the limiting speed becomes lower (see Fig. 5.2). Jacket cooling also affects the clearance between the bearing and the housing (see Fig. 5.3). Therefore, the clearance between the bearing and the housing could become negative, in which case the preload would be increased.

Fig. 5.2 The Influence of the Jacket Cooling on Limiting Speed

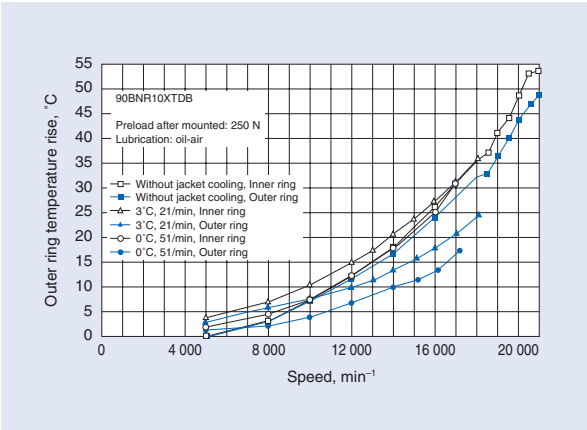

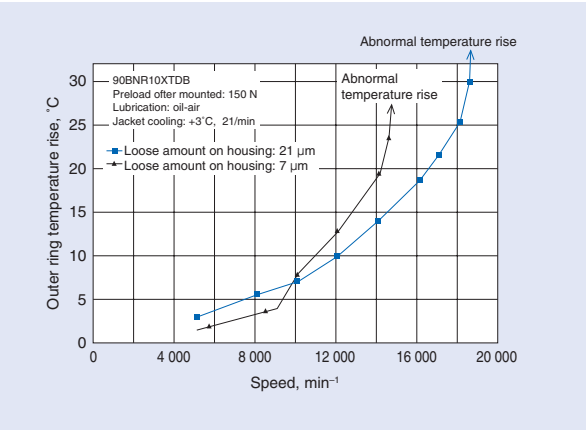

Fig. 5.3 The Influence of the Clearance between the Bearing & the Housing on Limiting Speed

Purposes of Lubrication

The main purposes of lubrication are to reduce friction and wear inside the bearing that may cause premature failure. The effects of lubrication may be briefly explained as follows:

(1) Reduction of Friction and Wear

Direct metallic contact between the bearing rings, rolling elements, and cage, which are the basic parts of a bearing, is prevented by an oil film which reduces the friction and wear in the contact areas.

(2) Extension of Fatigue Life

The rolling fatigue life of bearings depends greatly upon the viscosity and film thickness between the rolling contact surfaces. A heavy film thickness prolongs the fatigue life, but it is shortened if the viscosity of the oil is too low so the film thickness is insufficient.

(3) Dissipation of Heat

Circulating lubrication may be used to carry away frictional heat or heat transferred from the outside to prevent the bearing from overheating and oil from deteriorating.

(4) Others

Adequate lubrication also helps to prevent foreign material from entering the bearings and guards against corrosion or rusting.

Lubricating Methods

For machine tool spindles in which high accuracy is important, it is necessary to prevent excessive temperature rise of the spindle to reduce thermal deformation.

Bearing heat generation is divided into a load term determined by the bearing type and load, and a speed term determined by the lubricating method and speed.

Generally, the speed term is greater, but if a lubricating method resulting in a small speed term is selected, the influence of the load term cannot be disregarded. Therefore, it is important to select a low heat generating bearing (load term) and lubricating method (speed term).

Regarding heat generation, both the lubrication method and quantity of lubricant have important effects. Lubrication using a small amount of grease is common since this method is economical, maintenance free, and there is little heat generation. At high speeds, to maintain a constant low temperature, the oil-air lubrication method, which requires a minimum quantity of oil, was developed.

The relation between oil quantity and heat generation (frictional loss) and temperature rise is already known as shown in Fig. 6.1. Therefore, for machine tool spindles, to avoid excessive temperature rise, adoption of a lubricating method aiming at either zone A or B is necessary.

The lubricating methods in zones A and B are summarized in Table 6.1.

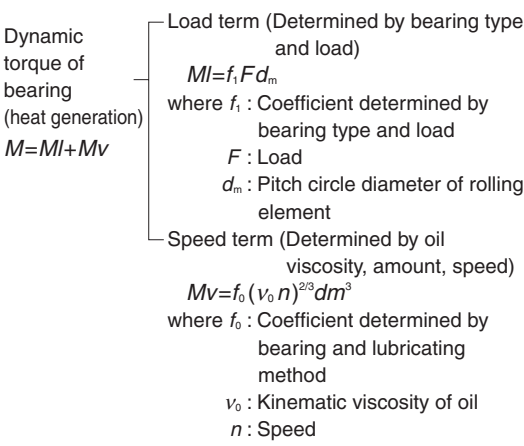

Fig. 6.1 Oil Quantity and Temperature Rise

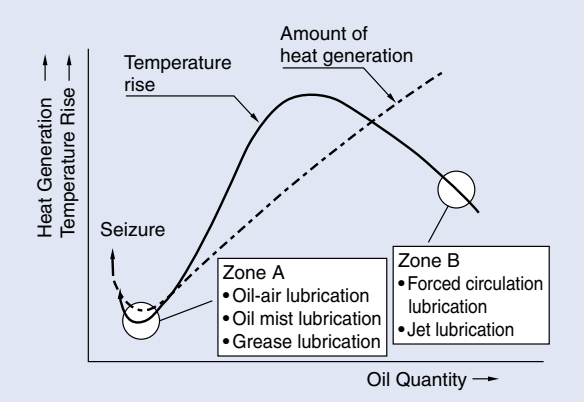

Table 6.1 Comparison of Lubricating Methods

Lubricating Methods	Advantages	Disadvantages
Grease Lubrication	<input type="checkbox"/> Cost is low. <input type="checkbox"/> Limitation of temperature rise is possible. <input type="checkbox"/> Maintenance free.	<input type="checkbox"/> If packed grease deteriorates, seizure may occur. <input type="checkbox"/> May allow penetration of dust or cutting fluid.
Oil Mist Lubrication	<input type="checkbox"/> Since new oil is always fed, no fear of oil deterioration. <input type="checkbox"/> Dust and cutting fluid cannot easily enter.	<input type="checkbox"/> Pollution of environment. <input type="checkbox"/> Oil supply quantity varies depending on the oil viscosity and temperature, so control of a small flow rate is difficult. <input type="checkbox"/> It is difficult to confirm that oil is actually fed.
Jet Lubrication	<input type="checkbox"/> Since the oil flow rate is high, dust and cutting fluid cannot enter and seizure hardly ever occurs. <input type="checkbox"/> Because of cooling by oil, the bearing temperature can be controlled to some degree.	<input type="checkbox"/> Frictional loss is high. <input type="checkbox"/> Since oil leaks, it is difficult to use for vertical spindles. <input type="checkbox"/> Cost is high.
Oil-Air Lubrication	<input type="checkbox"/> Since oil quantity control is possible, the optimum quantity of oil is fed and heat generation is low. <input type="checkbox"/> Besides little heat-generation, there is a cooling effect of the air, so the temperature is low. <input type="checkbox"/> Since new oil is always fed, no fear of oil deterioration. <input type="checkbox"/> Dust, cutting fluid cannot easily enter. <input type="checkbox"/> Environmental pollution mist is slight.	<input type="checkbox"/> Cost is rather high. <input type="checkbox"/> Confirmation of whether oil is actually fed to bearing is difficult.

Grease Lubrication

(1) Recommended Greases

Lithium base greases with mineral oil as the base oil have good sticking properties and excellent characteristics for rolling bearings. These are usually usable over a temperature range of -10°C to +110°C.

As grease for high speed machine tool spindles that require low temperature rise and long life, a consistency No.2 grease with a synthetic base oil (diester, diester + mineral oil, etc.) is recommended.

Table 6.2 lists the brand names and properties of greases widely used in machine tools main spindles and ball screw support bearings.

(2) Grease Life

Grease life depends greatly upon operating temperature; therefore, it is necessary to keep the temperature of the bearing (including atmospheric temperature) cooler, in order to extend the grease life.

High performance wide range grease is often used for high

speed spindle bearings, or spindle motor bearings.

The following equation shows the mean life of wide range grease:

$\log t=6.12-1.4n/N_{\max}-(0.018-0.006n/N_{\max}) T$

where  $t$ : Mean Grease life (h)

$N_{\max}$ : Limiting speed (min<sup>-1</sup>)

$n$ : Operating speed (min<sup>-1</sup>)

$T$ : Bearing running temperature (°C)

(3) Quantity of Grease for High Speed Spindle Bearings

To operate bearings at high speed with grease lubrication, the recommended quantity to be packed is 10% to 20% of internal space. If too much grease is packed, during running in, abnormal heat generation occurs and this may cause the grease to deteriorate. To avoid such a risk, it is necessary to run in spindles for a sufficient time. Based on their experience, NSK determines the packing quantity which allows easy running in and will provide sufficient lubrication. For the amount, please refer to the tables on Page 175.

Table 6.2 Grease Brand Names and Properties

Brand names	Manufacturers	Thickeners	Base oils	Base oils viscosity mm <sup>2</sup> s(40°C)	Dropping point (°C)	Working temperature range, (°C)	Main application
MTE	NSK	Barium complex	Ester oil	23	200	-30 to +120	Bearings for high speed spindles, high speed cylindrical roller bearings

Isoflex NBU15	Klüber	Barium complex	Diester oil + Mineral oil	20	250	-30 to +120	Bearings for main spindles
Multemps PS No.2	Kyodo Yushi	Lithium	Diester oil + Mineral oil	16	189	-50 to +110	Bearings for main spindles
Mobilux 2	Mobil	Lithium	Mineral oil	26	196	-10 to +110	Bearings for boring heads, live centers
Multemp LRL3	Kyodo Yushi	Lithium	Polyol ester oil	37	208	-30 to +130	Bearings for main spindles
Stabragus NBU8EP	Klüber	Barium complex	Mineral oil	105	220	-30 to +130	Heavy load cylindrical roller bearings
Alvania 2	Shell	Lithium	Mineral oil	130	182	-10 to +110	Ball screw support bearings
ENS	NSK	Urea	Polyol ester oil	32	260	-40 to +160	Bearings for motors
WPH	NSK	Diurea	Poly-α-olefin oil	96	259	-40 to +150	Ball screw support bearings

Oil Lubrication

(1) Oil Mist Lubrication and Oil-Air Lubrication (Minimal Oil Quantity Lubrication)

Spray oiling is a method of spraying oil by turning it into a mist using compressed air. It is also called oil mist lubrication. Oil-air lubrication is a method of feeding oil continuously by injecting oil into a compressed air stream by means of a mixing valve that intermittently discharges the minimum quantity of oil using a constant-quantity piston. Fig. 6.2 shows the recommended oil quantity for the lubrication methods described above, each quantity is for one bearing. In case of oil mist lubrication, it's necessary to adjust the oil quantity to accommodate for the effects of the branches in path tubing, and leakage from the gaps around the spacers. Please ask NSK, as the oil quantity should be increased, in cases where the  $d_m n$  value is higher than 1 800 000. For the position of the spray nozzle, please refer to Page 192.

(2) Jet Lubrication

Jet lubrication is mainly used for high speed bearings with a  $d_m n$  value  $100 \times 10^4$ . Through one to several nozzles, jets of lubricating oil under a constant pressure pass through the bearings. At high speed, the air surrounding the bearing rotates together with the bearing and forms an air wall. The speed of the jet from each nozzle must be faster by 20% than the circumferential speed of the inner ring outside surface. Since the jet lubrication uses a large quantity of oil, there is much agitation resistance, so it is necessary to dissipate the heat effectively using a large oil discharge outlet and forced discharge. For machine tool spindle bearings, this method is used in some applications as a means for stable operation at ultra high speeds (see Fig. 6.3). For the position of the spray nozzle, please refer to page 192.

The grease quantity of "xxTAC20(29)X(D)" should be same as the double row cylindrical roller bearing's, which is assembled with this bearing together. Use the grease listed on Page 173, and multiply 0.93 (density) to the quantity above, for the weight of the grease. For the recommended grease quantity for angular contact thrust ball bearing for ball screw support, please refer to Page 110-113.

7. BEARING TOLERANCES

The tolerance for the boundary dimensions and running accuracy of NSK radial bearings are specified by the Accuracies of Rolling Bearings in ISO 492/199/582/1132-1, and Rolling Bearing Tolerances in JIS B 1514. In addition to the above tolerances, NSK manufactures angular contact ball bearings with precision classes ABEC 5, 7, and 9 as specified by American Bearing Manufacturers Association (ABMA) Standard 20.

Rough definitions of the items listed for running accuracy and their measuring methods are described in Fig. 7.1 and Table 7.1. Further details are available in ISO 5593, Rolling Bearings Vocabulary in JIS B 0104, and Measuring Methods for Rolling Bearings in JIS B 1515.

Table 7.1

Running Accuracy	Inner Ring	Outer Ring	Dial Gauge
Radial runout of assembled bearing inner ring $K_{ia}$	Rotating	Stationary	A
Radial runout of assembled bearing outer ring $K_{ea}$	Stationary	Rotating	A
Assembled bearing inner ring face (backface) runout with raceway $S_{ia}$	Rotating	Stationary	$B_1$
Assembled bearing outer ring face (backface) runout with raceway $S_{ea}$	Stationary	Rotating	$B_2$
Inner ring reference face (backface, where applicable) runout with raceway $S_d$	Rotating	Stationary	C
Variation of bearing outside surface generatrix inclination with outer ring reference face (backface) $S_D$	N/A	Rotating	D

(1) Applicable to individual rings manufactured for combined bearings.

(2) Applicable to bearings with cylindrical bores.

(3) Class 3 is NSK's original accuracy. Tolerance of bearing bore diameter and outer ring diameter are Class 4. Other tolerances are Class 2.

(4) Applicable to ball bearings.

Remarks: 1. The cylindrical bore diameter tolerance limit (high), as per the no-go side of a plug gauge as specified in this table, is not necessarily applicable within a distance of 1.2 times the chamfer dimension  $r$  (max.) from the ring face.

2. ABMA Standards ABEC5, ABEC7, and ABEC9 are equivalent to ISO (JIS) Classes 5, 4, and 2 respectively.

ABMA Standards are applicable to angular contact ball bearings.

Inner ring (Class 4Y)

(As for Class 4Y (P4Y), bore diameter dimensional accuracy and outside diameter dimensional accuracy are special.)

Table 7.6 Tolerance of Bore Diameter of Inner Ring

\* Tolerances for bearings under 30 mm bore are the same as values quoted for bearings with bores between 30–50 mm.

Class 4Y is NSK's proprietary accuracy standard, in which tolerance of a bearing bore diameter and an outer ring diameter are in a special class (controlled to medium value) and other tolerances are Class 4. Class 4Y has the same running accuracy as Class 4 but has a narrower tolerance range of bore and outer diameter than Class 4. It is suitable for universal combination bearings.

Bore diameter (mm)		Class 4		Class 4Y (Controlled to medium value)	
		high	low	high	low
30	50	0	− 6	−1	−3
50	80	0	− 7	−2	−5
80	120	0	− 8	−3	−6
120	150	0	−10	−3	−7

(<sup>1</sup>) Applicable to ball bearings.  
(<sup>2</sup>) Class 3 is NSK's original accuracy. Tolerance of bearing bore diameter and outer ring diameter are Class 4. Other tolerances are Class 2.

Remarks: 1. The cylindrical bore diameter tolerance limit (high), as per the no-go side of a plug gauge as specified in this table, is not necessarily applicable within a distance of 1.2 times the chamfer dimension r (max.) from the ring face.  
2. ABMA Standards ABEC5, ABEC7, and ABEC9 are equivalent to ISO (JIS) Classes 5, 4, and 2 respectively.  
ABMA Standards are applicable to angular contact ball bearings.

150	180	0	− 10	− 3	− 7
180	200	0	− 11	− 4	− 9
200	215 and less	0	− 11	− 2	− 9

\* Tolerances for bearings under 50 mm outer diameter are the same as values quoted for bearings with outer diameters between 50–80 mm.  
Class 4Y is NSK's proprietary accuracy standard in which tolerance of a bearing bore diameter and an outer ring diameter are in a special class (controlled to medium value) and other tolerances are Class 4. Class 4Y has the same running accuracy as Class 4 but has a narrower tolerance range of bore and outer diameter than Class 4. It is suitable for universal combination bearings.

Tolerances for Tapered Bores of Cylindrical Roller Bearings

Tolerances for Tapered Bores

The bore accuracy of tapered bore cylindrical roller bearings is specified by ISO. However, in this standard, the tolerances are rather wide. For precision-class cylindrical roller bearings, NSK established its own narrower tolerances. As is customary, however, two taper angles are available within the tolerance range specified by ISO (see Fig. 7.2).

(NSK terminated production of K tapered bore cylindrical roller bearings and is producing only KR tapered bore cylindrical roller bearings.)

Tolerances for Angular Contact Ball Bearing for Ball Screw Support

Machine Tool Applications

Table 7.18 TAC B series Unit: μm

Nominal Bore or Outside Diameters (mm)		Deviation of Bore Diameter				Deviation of Outside Diameter				Deviation of Inner Ring Width		Inner or Outer Ring Runout with Raceway
		Tolerance Classes				Tolerance Classes				Tolerance Classes		
		PN7A		PN7B		PN7A		PN7B		PN7A PN7B		
over	incl	high	low	high	low	high	low	high	low	high	low	max.
10	18	0	−4	0	−4	−	−	−	−	0	−120	2.5
18	30	0	−5	0	−4	−	−	−	−	0	−120	2.5
30	50	0	−6	0	−4	0	−6	0	−4	0	−120	2.5
50	80	0	−7	0	−5	0	−7	0	−5	0	−150	2.5
80	120	0	−8	0	−6	0	−8	0	−6	0	−200	2.5

Remark: Variation of outer ring width is the same as that for the inner ring of the same bearing.

Class PN7A is the standard tolerance for these bearings. This corresponds to ISO Class 4 for radial ball bearings, but for the runout of the inner and outer rings, more stringent values are applied.

The stricter Class PN7B applies to the dimensional tolerances of the bores and outside diameters of single-row universal arrangement bearings (SU).

Electrical Injection Molding Machine

Table 7.19 TAC 02 and 03 series Unit: μm

Nominal Bore or Outside Diameter (mm)		Deviation of Bore Diameter		Deviation of Outside Diameter		Deviation of Inner Ring Width		Inner or Outer Ring Runout with Raceway
		Tolerance Class						
		PN5D						
over	incl	high	low	high	low	high	low	max.
10	18	0	− 5	−	−	0	− 80	5
18	30	0	− 6	−	−	0	−120	5
30	50	0	− 8	0	− 7	0	−120	5
50	80	0	− 9	0	− 9	0	−150	8
80	120	0	−10	0	−10	0	−200	8
120	150	−	−	0	−11	−	−	−
150	180	−	−	0	−13	−	−	−
180	250	−	−	0	−15	−	−	−
250	315	−	−	0	−18	−	−	−

Remark: Variation of outer ring width is the same as that for the inner ring of the same bearing.

Class PN5D is the standard tolerance for these bearings. This corresponds to ISO Class 5 for radial ball bearings, but for the runout of the inner and outer rings, more stringent values are applied.

Fitting of Shafts and Housings

It is of utmost importance that shafts and housings are accurately and precisely mated in order to take full advantage of the precision bearings' capabilities, which include rotational accuracy, high speed performance, and low heat generation.

When the inner ring or outer ring is mounted onto a shaft or into a housing with some interference, the shape of shaft or housing (out of roundness) is transferred to the bearing raceway surfaces and affects running accuracy. When multiple angular contact ball bearings are used, cylindricity affects the distribution of preload for each bearing. Therefore, the mating parts should be as accurate as possible.

Inaccurate mating of parts can cause the formation of peaks or ridges along the shaft of a precision lathe, which can affect the quality of finished work.

(°) The fitting data above provides general recommendations for machine tool spindles operating under normal conditions and for  $d_{pr}n$  values of less than 800,000. For high speeds, heavy loads, or outer ring rotation, please contact NSK for assistance.

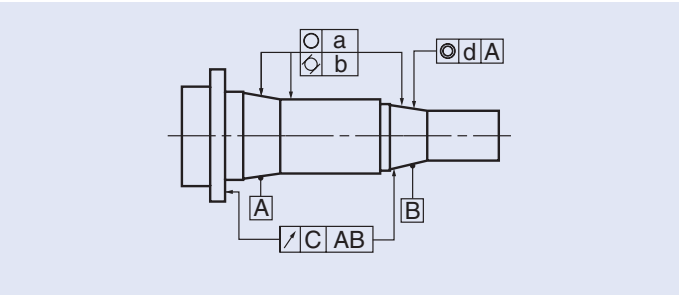

(°) Use the target interference when the bearing can be matched to the shaft or housing, Otherwise, use the shaft outer diameter and housing bore minimum and maximum for random matching.

(°) Applies to angular contact ball bearings: 70XX, 79XX, 72XX, BNR and BER  
Angular contact thrust ball bearings: BAR, BTR and TAC  
Cylindrical rollers bearings: N10XX, NN30XX, NN39XX, NN49XX and NNU49XX.

(°) T=Interference or tight fit  
L=Clearance or loose fit

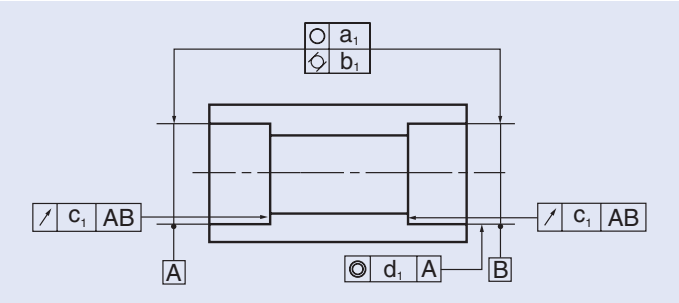

If the taper of the inner ring for a double row cylindrical roller bearing with a tapered bore does not match that of the shaft, the residual clearance will be different for two of the rows. Therefore, load will not be sustained normally, and will impair rigidity or cause irregular movement of the rollers due to taper of the inner ring groove. We recommend that you gauge the tapered parts to be mated with bearings. Contact should cover more than 80% of the total surface area that is dyed blue. The recommended accuracy and surface roughness of bearing mounting seats are shown in following tables:

Fig. 8.1 Figure of Shoulder and Fillet Dimension

Chamfer Dimension Limits and Corner Radius of Shaft or Housing

Fig. 8.2 Chamfer Dimension

Remarks: The precise shape of chamfer surfaces has not been specified but its profile in the axial plane shall not intersect an arc of radius  $r$  (min.) or  $r_1$  (min.) touching the side face of an inner ring and bore surface, or the side face of an outer ring and outside surface.

Table 8.7 Chamfer Dimension Limits Unit: mm

Permissible Chamfer Dimension for Inner/Outer Rings $r$ (min.) or $r_1$ (min.)	Nominal Bore Diameter $d$		Permissible Chamfer Dimension for Inner/Outer Rings $r$ (max.) or $r_1$ (max.)		Reference Corner Radius of Shaft or Housing $r_a$

19	—	—	25	38	15

(1) For bearings with nominal widths less than 2 mm, the value of  $r$  (max) in the axial direction is the same as that in the radial direction.

Spacer Dimensions

The dimensions of standard spacers for angular contact ball bearings (19, 29, 10, 20 and 02 series) are listed below:

Additional information:

Material of spacer: Steel (SUJ2) or S \*\* C steel

When using spacers, parallelism of spacer end surfaces should be less than 0.003 mm.

19 or 29 Series **Standard Spacers for Dimension Series 19 or 29 (79, BNR19, BER19, BNR29, BER29, BGR19)** Unit: mm

Bore Numbers	Nominal Bore Diameter	Outer Diameter	Outer Ring Spacer		Inner Ring Spacer		Spacer Chamfer

40	200	280	279.2	255	225	200.8	1.0

(1) For outer ring spacers operating under oil mist lubrication or jet lubrication, the outer diameter of the outer ring spacer is the same as that of the bearing outside diameter. Recommend maintaining a tolerance of g5 or better.

(2) For high speed operations exceeding a value of  $d_{mn} 70 \times 10^4$ , the bore diameter of the inner ring spacer is the same as that of the bearing bore. Recommend maintaining a tolerance of F6 or better.

Additional information:

Material of spacer: Steel (SUJ2) or S \*\* C steel

When using spacers, parallelism of spacer end surfaces should be less than 0.003 mm.

10 or 20 Series

Standard spacers for dimension series 10 or 20 (70, BNR10, BER10, BNR20, BER20, BGR10)

Unit: mm

Bore Numbers	Nominal Bore Diameter	Outer Diameter	Outer Ring Spacer		Inner Ring Spacer		Spacer Chamfer
			Outer Diameter (¹)	Bore	Outer Diameter	Bore (²)	
00	10	26	25.5	21.5	14.5	10.5	0.2

40	200	229.0	0.7	240.9	2.5	—	—	—	—	—	—

(°) In compliance with DIN Standard 628-6.

Attention

- For bearings operating under normal operating speed, proper lubrication can be achieved by positioning the nozzle bore along the side of the bearing and aiming directly into the bearing interior at the level of the inner ring. For constant high speed operations, it is advantageous to position the nozzle bore so that the lubricant is directed into the bearing interior at an angle of about 15°or 20°. Please contact NSK for further details.
- An appropriate means of draining oil sump is necessary to prevent severe oil shear friction, which can result in bearing damage at the sliding section.
- Recommend using a maximum 5 micron filter to provide filtration of oil entering the lubricating system.

*Bearing Handling*

# Introduction

## Mounting Procedure

The method of mounting rolling bearings strongly affects their accuracy, life, and performance. It is recommended that the handling procedures for bearings be fully analyzed by designers and engineers and that standards be established with respect to following items:

- 1. Cleaning the bearings and related parts
- 2. Checking the dimensions of related parts
- 3. Mounting procedures
- 4. Inspection after mounting

Bearings should not be unpacked until immediately before mounting. However, bearings for instruments or for high speed operations must first be cleaned with clean filtered oil in order to remove the anti-corrosion agent.

After the bearings are cleaned with filtered oil, they should be protected to prevent corrosion. Prelubricated bearings must be used without cleaning.

Bearing mounting procedures vary according to the type of bearing and type of fit.

Since precision bearings are widely used for rotating shafts, their inner rings require a tight fit.

Bearings with cylindrical bores are usually mounted by fitting with a press (press fit), or by heating them to expand their inner ring (shrink fit). The outer ring is usually inserted into the housing with a loose fit. In case where the outer ring has an interference fit, a press may be used.

## Precautions for Proper Handling of Bearings

Since rolling bearings are high precision machine parts, they must be handled accordingly. Even if high quality bearings are used, their expected performance cannot be achieved if they are not handled properly. The main precautions to be observed are as follows:

### ■ Keep bearings and surrounding area clean

Foreign particles, even if invisible to the naked eye, have harmful effects on bearings. Take care to prevent the entry of dirt and debris into the bearing by maintaining a clean working environment.

### ■ Handle bearings carefully

Avoid any heavy shocks during handling. Shock loads can scratch or otherwise damage a bearing, possibly resulting in failure. An excessively strong impact may cause brinelling, breakage, or cracks.

### ■ Use proper tools

Always use the proper equipment when handling bearing. Do not use general purpose tools.

### ■ Prevent corrosion

Handling bearings with bare hands can corrode the bearing surfaces because of the acidic moisture or other contaminations on the hands.

Keep your hands clean when handling bearings, and wear dust free gloves whenever possible. Take measures to prevent rusting of bearings caused by moisture and corrosive gasses.

## Storage method

■ Although bearings are coated with an anti-corrosion agent, and then wrapped and packed, it is impossible to completely avoid exposure to the air surrounding the bearings. Store the bearings in a dry location and avoid exposure to moisture and humidity.

■ Bearings should be stored in a clean, dry, and well-ventilated location that also provides protection from direct sunlight. Store the bearings in a locker or on shelves that are at least 30 cm from the floor.

■ When bearings are unpacked for acceptance inspection, take measures to prevent rusting and contamination. After inspection, follow the guidelines given above to ensure proper storage.

## 1. Cleaning the Bearings and Related Parts

Delivered bearings are coated with an anti-corrosion agent for dustproofing and rust prevention during transportation.

After opening the package, bearings need to be cleaned in order to remove the anti-corrosion agent.

Some bearings, such as sealed or pregreased bearings, can be used without cleaning.

### ■ Cleaning method ■

1. Use kerosene or light oil to clean the bearings.
2. Use separate tanks for rough cleaning and final cleaning. Each tank should be equipped with a wire rack to prevent direct contact of the bearing with any contamination that may have settled at the bottom.
3. In the rough cleaning tank, avoid rotating the bearings. After cleaning the outside surfaces with a brush, move the bearings to the final cleaning tank.
4. In the final cleaning tank rotate the bearing by hand. Make sure that the cleaning fluid in the final cleaning tank is kept clean.
5. Remove excess cleaning fluid from the bearings after cleaning. Bearings using ordinary grease lubrication need to be packed with grease. Oil lubricated bearings should be mounted on the machine tool spindle while taking care not to rotate the bearing. Prior to mounting, slightly coat the bearing inner and outer surface areas with a thin film of lubrication oil.

## 2. Checking Dimension of Related Parts

### Inspection of shaft and housing

- Mating housing and shaft surfaces should be cleaned and checked for flows or burrs.
- The dimensions of the shafts and housing bores should be checked to confirm a matching fit with the bearing bore and outer diameter. Recommended fits for shafts and housing bores are listed on Page 184.
- Take measurements and mount the bearings in a thermostatic chamber. Parts should be left until they have

reached a constant and stable temperature. Using a micrometer or cylinder gauge, take measurements at several different points to confirm there are no significant differences in measurement values. Recommended measurements for accuracy of the shafts and housing bores are listed on Page 185.

### Inspection of spacers

For main spindle, a spacer parallelism of less than 0.003 mm is recommended. Spacer parallelism exceeding this recommendation will tilt the bearings, thus causing inaccuracies and bearing noise.

## 3. Mounting Procedures

Grease lubricated bearings and oil-air (oil mist) lubricated bearings which are cleaned are mounted on the shaft and housing bore. Procedures for mounting vary according to the fit requirements of the inner and outer rings. Primarily, it is the inner ring of a machine tool bearing that rotates, thus bearings with cylindrical bores are usually mounted by heating them to expand the inner ring (shrink fit).

Bearing with tapered bores can be mounted directly onto a tapered shaft. For high speed operations, GN gauges are recommended for attaining accurate radial clearance when mounting. Page 202 provides details on how to use GN gauges.

Outer rings are mounted with some clearance; so mounting tool are not usually required. The housing can be heated to make mounting much easier.

3.1. Mounting of Bearings with Cylindrical Bores  
(1) Press fit

Fitting with a press is widely used for small bearings. First, apply a thin coat of oil to the mating shaft surface before mounting to help reduce the amount of force required for press fitting.

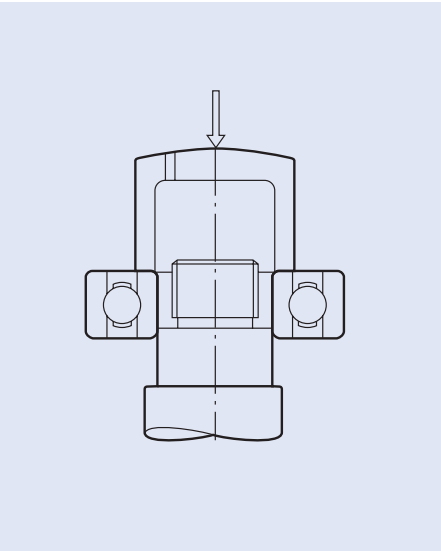

Next, place a mounting tool against the inner rings as shown in Fig. 1.1. Apply steady pressure from the mounting tool to drive the bearing firmly against the shoulder of the shaft.

Avoid press fitting onto a shaft by applying pressure to the outer rings as this may damage the bearing.

Also, avoid using a hammer when mounting precision bearings.

For separable bearings, such as cylindrical roller bearings, the inner and outer rings can be mounted onto the shaft and into the housing as separate units. When assembling the two units, take extra care to align the inner and outer rings correctly. Careless or forced assembly may cause scratches on the rolling contact surfaces.

Fig. 1.1 Press Fitting Inner Ring

(2) Shrink fit

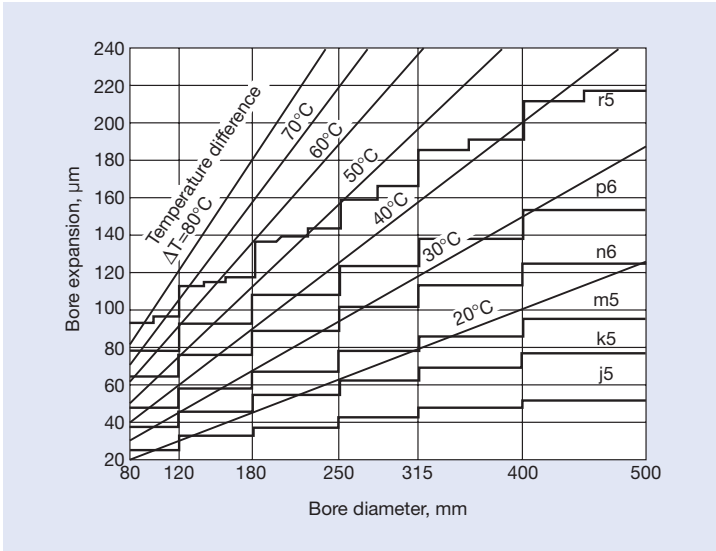

Since press fitting large bearings requires a great deal of force, the shrink fitting method is widely used. The bearings are first heated to expand the inner ring before mounting onto the shaft. This method prevents excessive force from being imposed on the bearings and enables mounting them in a short time.

The expansion of the inner ring for various temperature differences and bearing sizes is shown in Fig. 1.2.

The following precautions need to be taken when shrink fitting.

1. Do not heat bearings to more than 120°C.
2. Heat the bearings to a temperature 20°C to 30°C higher than the lowest temperature required for mounting without interference since the inner ring will cool a little during mounting.
3. After mounting, the bearings will shrink in the axial direction as well as the radial direction while cooling. Therefore, drive the bearing firmly up against the shaft shoulder using locating methods to eliminate any clearance between the bearing and shoulder.

Fig. 1.2 Temperature and Thermal Expansion of Inner Ring

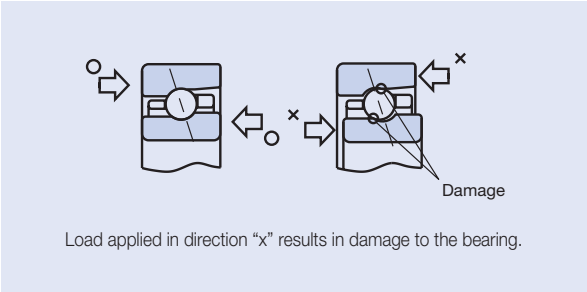

3.2. Precautions for Mounting Angular Contact Ball Bearings  
Contact Ball Bearings

Due to design restriction, an angular contact ball bearing can sustain loads in only one direction. Therefore, when mounting angular contact ball bearings onto the shaft or into the housing, it is important not to apply any load in the wrong direction.

Pay special attention to the order of mounting for combination bearings. Mounting onto the shaft and into the housing is different for Back-to-back and Face-to-face arrangements.

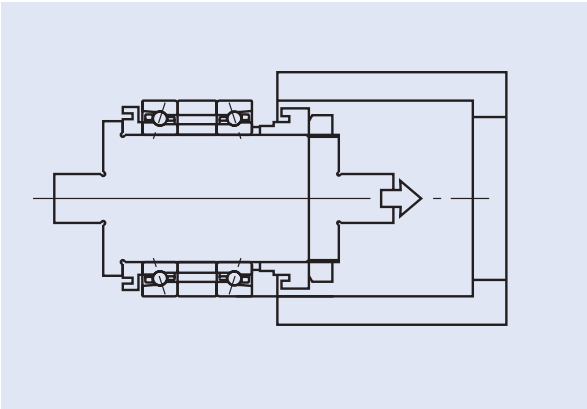

Fig. 1.3 Direction of Load for Angular Contact Ball Bearings

Back-to-back arrangement:

- ① Press the bearing onto the shaft.
- ② Tighten the bearing locknut for preloading.
- ③ Insert the bearing and the shaft into the housing, and attach the retaining cover.

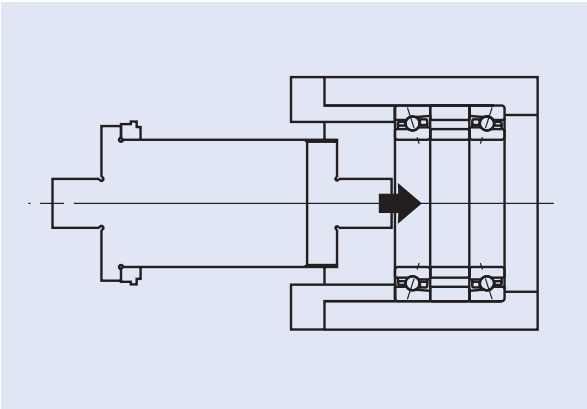

Fig. 1.4 Mounting of Back-to-back Arrangement

Face-to-face arrangement:

- ① Press the bearing into the housing.
- ② Secure the retaining cover for preloading.
- ③ Insert the shaft into the inner ring and tighten the bearing locknut.

Fig. 1.5 Mounting of Face-to-face Arrangement

Reverse the order of each step for dismounting.

3.3. Securing the bearing  
(1) Securing the inner ring

The inner ring is usually secured onto the shaft by tightening the bearing locknut, which explains why perpendicularity of the threads and end face are very important. Even if accuracy as a single component is good, the gap between the shaft and locknut can result in runout of the locknut, causing the shaft and bearing to bend (see Fig. 1.21, Page 207). Therefore, making adjustments are necessary to ensure constant running accuracy.

It is also important that the locknut be completely tightened so as to eliminate any possibility of it becoming loose. Seating torque information for bearing locknuts is shown in Table 1.1.

There is a risk of unbalance due to face and runout of the locknut or a minor inaccuracy of the mating parts. Here, sleeves are widely used in high speed, high precision machine tool spindles to secure the bearing to the shaft by a large interference fit between the shaft and sleeve bore. However, the sleeve tends to become loose after continuous operation, so it must be checked periodically.

When a wide spacer is used between combined angular contact ball bearings, and the seating torque of the locknut is excessive, the inner ring spacer may become deformed and alter the preload to a level higher than expected. It is necessary to consider this deformation when the preload is set.

(2) Securing the outer ring

A retaining cover held by bolts is generally used to secure the bearing outer ring axially. If a bolt is tightened excessively or a combination of bolts is tightened unevenly, the bearing outer ring may become deformed.

For example, Fig. 1.6 shows possible deformation of the outer diameter of the outer ring caused by uneven tightening of the retaining cover, when the outer ring end face is pressed as a pilot ring.

Fig. 1.7 shows an example of poor retaining cover tightening for a fixed end bearing resulting in outer ring deformation.

Fig. 1.8 shows deformation of an outer ring raceway surface caused by tightening of a double row cylindrical roller bearing.

The amount of deformation depends on the clearance of the mating parts. It is recommended that the clearance between the retaining cover and housing end face be adjusted to about 0.01 to 0.05 mm before the bolts are completely tightened.

Fig. 1.6 Raceway Surface Deformation Caused by Excessive Tightening

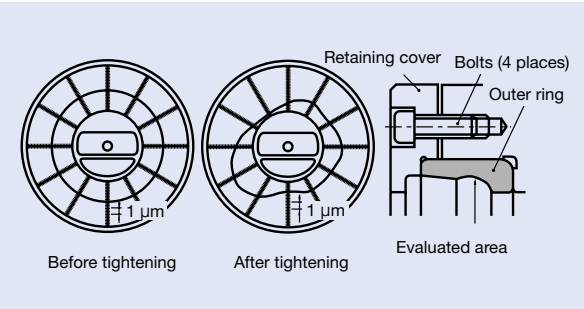

Fig. 1.7 Raceway Surface Deformation Caused by Excessive Tightening

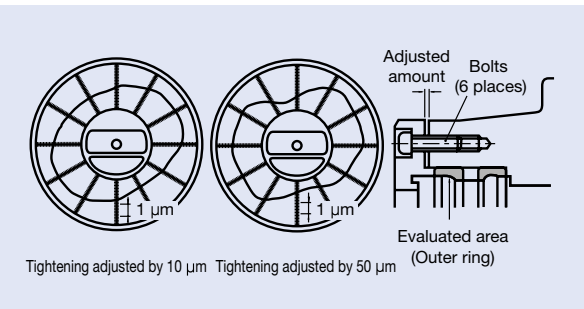

Fig. 1.8 Deformation of the Outer Ring of a Double Row Cylindrical Roller Bearing Caused Excessive Tightening

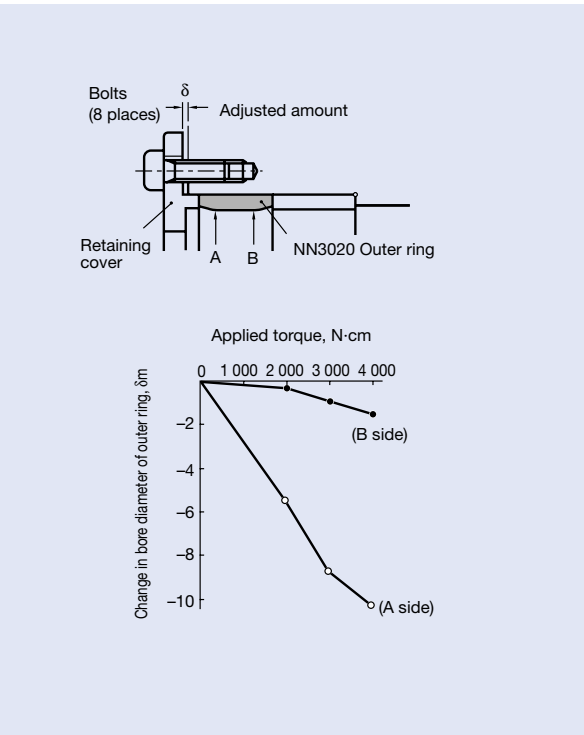

Table 1.1 Bearing Locknut Tightening Torque and Clearance between Retaining Cover and Housing

Nominal bearing bore (mm)	Locknut tightening force (N)	Locknut tightening torque Reference (N·m)	Clearance between retaining cover and housing (mm)

When interference fit of the shaft increases under high speed operations, the amount of tightening torque applied to the locknut must also be increased.

The tightening force of angular contact thrust ball bearing for ball screw support should be 2.5–3.0 times of the preload.

■ Conversion equation of locknut tightening torque

$$T=0.5F \left\{ d_p \cdot \tan (\rho^*+\beta)+d_w \cdot \mu_w \right\} \quad [\text{N}\cdot\text{mm}]$$

The values of locknut tightening torque in the table are calculated by friction coefficient of 0.15.

- $T$  :Locknut tightening torque [N·mm]
- $F$  :Locknut tightening force [N]
- $d_p$  :Effective diameter of locknut [mm]
- $\rho^*$  :Friction angle of locknut surface  
 $\rho^*=\tan^{-1} \mu_s$
- $\mu_s$  :Friction coefficient of locknut surface
- $d_w$  :Frictional torque equivalent diameter at locknut surface [mm]
- $\mu_w$  :Friction coefficient of locknut surface
- $\beta$  :Lead angle of nut  
 $\beta=\tan^{-1} (\text{pitch}/(3.142 \cdot d_p))$

■ Equation of push up force

$$K=\mu \cdot p_m \cdot \pi \cdot d \cdot B \quad [\text{N}]$$
$$p_m=\frac{E}{2} \frac{\Delta d}{d} \frac{(1-k^2)(1-k_o^2)}{1-k^2 k_o^2}$$

- $\mu$  :Friction coefficient at fitting surface [=0.12]
- $p_m$  :Surface pressure [MPa]
- $d$  :Shaft diameter [mm]
- $B$  :Bearing width [mm]
- $\Delta d$  :Effective interference [mm]
- $E$  :Young's modulus of steel [MPa]
- $k$  :Wall thickness ratio ( $k=d/D_i$ )
- $D_i$  :Raceway diameter of inner ring [mm]
- $k_o$  :Wall thickness ratio of hollow shaft ( $k_o=d_o/d$ )
- $d_o$  :Bore diameter of hollow shaft [mm]

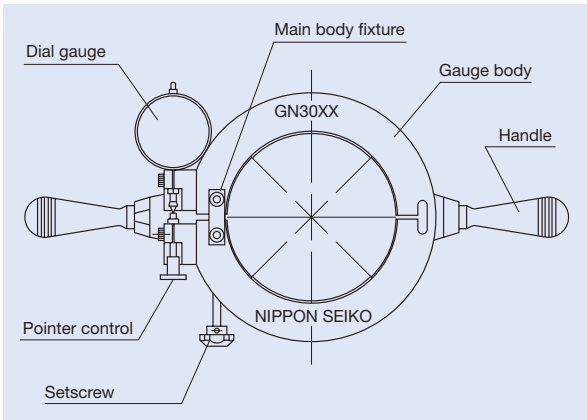

3.4. Mounting of Cylindrical Roller Bearings

(1) Measuring radial clearance of cylindrical roller bearings

A GN gauge is an instrument for matching the tapered section of a shaft to the tapered bore of a bearing when mounting a cylindrical roller bearing with a tapered bore onto a machine tool spindle. After mounting, the GN gauge is used for precise control of the bearing's radial internal clearance. This instrument is especially effective when a cylindrical roller bearing is used with radial preload.

Fig. 1.9 describes the GN gauge components.

Fig. 1.9 GN Gauge

How to use a GN gauge

① Insert outer ring into housing

The recommended fit between outer ring and housing is:

Clearance 2  $\mu$ m - Interference 2  $\mu$ m

② Zero setting of cylinder gauge

Confirm that the temperatures are the same for the outer ring (inserted into the housing), the inner ring, and the shaft. Then, measure the bore diameter of the outer ring at about four different locations. Determine the average for the measurements and the cylinder gauge to zero (see Fig. 1.10).

③ Adjust the inscribed diameter of GN gauge

Loosen the bolt of the main body fixture on the GN gauge. Apply the cylinder gauge to the inscribed diameter surface of the GN gauge and adjust the setscrew to the setting of the dial on the cylinder gauge to zero (see step ②).

(Use the GN gauge in an upright position to avoid inaccuracies due to its own weight.)

④ Correction of GN gauge

Using the results from step ③, use the pointer control on the dial gauge to adjust the pointer on the GN gauge to the red mark for gauge correction. Confirm that the short needle is near 2 on the dial.

(Gauge correction corrects for elastic deformation of the roller due to measuring pressure on the gauge. The amount of correction for each gauge is determined upon shipment a gauge.)

Fig. 1.10 Zero Setting of Cylinder Gauge

Fig. 1.11 Adjust the Inscribed Diameter of the GN Gauge

⑤ Mounting of inner ring

Mount the inner ring onto the shaft and tighten the locknut lightly. At this time, the bearings should be cleaned, but not yet coated with grease.

⑥ Setting of GN gauge

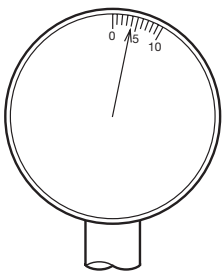

Adjust the setscrew on the GN gauge (0.2 mm to 0.3 mm on the dial face) to spread open the dial on the GN gauge. The GN gauge is placed in the center of inner ring and the setscrew is loosened.

⑦ Reading of the scale

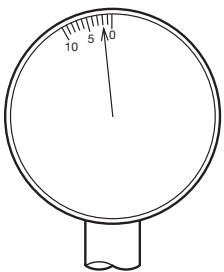

Read the scale on the dial gauge of the GN gauge at this time.

Example 1: A half-shift of the dial from zero in a clockwise direction indicates positive clearance.

Example 2: A half-shift of the dial from zero in a counter-clockwise direction indicates negative clearance.

Example 1: Pointing to "4" in a clockwise direction indicates a radial clearance of +0.002 mm

Example 2: Pointing to "2" in a counter-clockwise direction indicates a radial clearance of -0.001 mm

⑧ Adjustment

In addition to procedures given in step ⑥, use the screw to spread the dial of the GN gauge. Remove the gauge from inner ring and tighten the locknut. Repeat steps ⑥ through ⑧ until the scale of the dial gauge reaches the target clearance value.

⑨ Adjustment of spacer

Measure the clearance between the shaft shoulder and the end face on the large diameter side of NN30XXKR by using block gauge. Measure more than three places on circumference to both an average and the finish width of spacer for that average.

Fig. 1.12 Insertion of Inner Ring

Fig. 1.13 Setting of GN Gauge

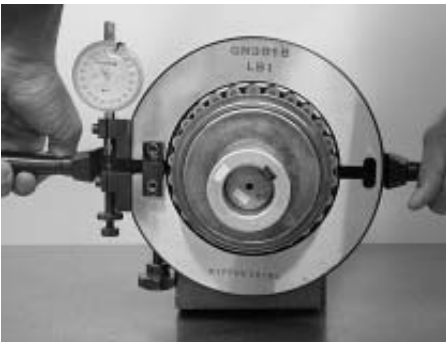

Fig. 1.14 Reading of the Scale

Fig. 1.15 Measurement of Spacer Width

(2) Measuring radial clearance of cylindrical roller bearings (GN gauge is not used)

When the GN gauge is not used, it is necessary to adjust the spacer width by considering the following two items:

- Shrinkage of outer ring raceway diameter due to fitting in housing ( $\Delta r_e$ )
- Expansion of the inner ring raceway diameter due to fitting, which includes a hollow shaft ratio ( $\Delta r_i$ )

■ Calculation of  $\Delta r$

The finish dimension ( $L_a$ ) of the spacer, which is used for setting the post-mounting radial clearance of  $\Delta r$ , can be calculated as follows:

$$L_a = L - K (\Delta r_m - \Delta r + \Delta r_e)$$

Table 1.2 Hollow Shaft Ratio and Coefficient  $K$

Hollow shaft Ratio $k_0$	Coefficient $K$
45–55%	14
55–65%	15
65–75%	16

- $L_a$  : Finish dimension of spacer for setting post mounting radial clearance
- $L$  : Width of block gauge (Measured result from step ⑤ on Page 205.)
- $\Delta r_m$  : Movement of the outer ring in radial direction (Measured result from step ④ on Page 205.)
- $\Delta r$  : Radial clearance after mounting
- $\Delta r_e$  : Shrinkage of outer ring raceway diameter due to fitting
- $K$  : Coefficient (Converted value which includes shrinkage of a hollow shaft with a 1/12 tapered hole)
- $k_0$  :  $A/B \times 100$   
A: Shaft bore diameter    B: Shaft outer diameter

■ Calculation of  $\Delta r_e$

$$\Delta r_e = (D_h - D) \times h$$

when  $\Delta r_e \geq 0$  assume  $\Delta r_e = 0$

- $D_h$  : Housing bore diameter
- $D$  : Outer diameter of outer ring (Refer to bearing inspection sheet)
- $h$  : Shrinkage rate of the outer ring raceway diameter  
(0.62 for NN30 and N10 series)  
(0.7 for NN39 and NN49 series)

Measuring of radial clearance of  $\Delta r_m$

- ① Mount the inner ring onto the tapered section of the shaft. (At this point, degrease the tapered section of the shaft and internal surface of the inner ring with organic solvent.)
- ② Place the outer ring on the circumscribing part of the rollers and apply the dial gauge to outer diameter of the outer ring.
- ③ Tighten the spacer and the locknut now to expand the inner ring (see Fig. 1.16).
- ④ Push the outer ring in up and down and measure the radial movement of the outer ring with dial gauge (\*). Repeat steps ③ and ④ until play of the outer ring ( $\Delta r_m$ ) becomes about 0.005 mm (\*) (Fig. 1.17).
- ⑤ When  $\Delta r_m$  is set at about 0.005 mm, measure the distance from shaft shoulder to the inner ring end face (Dimension  $L$ ) with block gauge and the thickness gauge (\*) (see Fig. 1.18).

Remarks

- (\*1) If the measurement takes too long, the temperature of the outer ring may have risen to body temperature resulting in an erroneous measurement. Wearing gloves is recommended to for making a quick measurement.
- (\*2) If there is an excessive amount of play, the outer ring may have deformed into an ellipse when pressed by hand. This would result in an erroneous measurement. Therefore, 0.005 mm of play is acceptable. (0.005 mm is the target value, but 0.001 mm to 0.002 mm is also acceptable.)
- (\*3) For the measurement of dimension  $L$ , the value obtained is produced by inserting the block gauge in the left half of the zone shown in Fig. 1.18 (This is due to tilting that occurs between the shaft shoulder and inner ring end face.)

Fig. 1.16 Insertion of Outer Ring

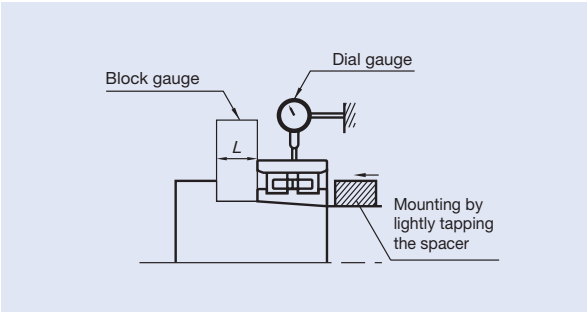

Fig. 1.17 Measuring Outer Ring Movement

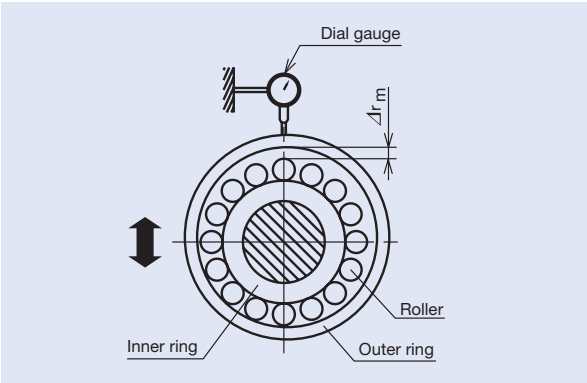

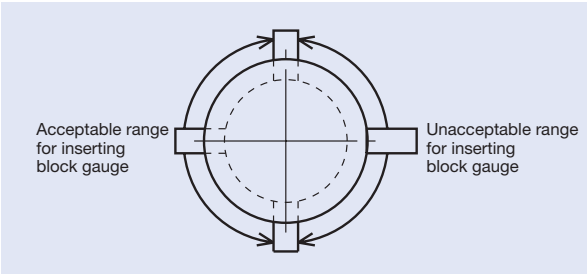

Fig. 1.18 Measuring Width Dimension with Block Gauge

(Example of calculation)

Setting radial clearance to  $\Delta r = -0.002$  mm for NN3020MBKR after mounting.

Shrinkage of outer ring raceway diameter due to fitting:  $\Delta r_e = -0.004$  (Interference) (When  $\Delta r_e \geq 0$  assume  $\Delta r_e = 0$ )

Movement of outer ring (Measured value in step ④):  $\Delta r_m = 0.007$  mm

Block gauge width (Measured value in step ⑤):  $L = 20.55$  mm

Finish spacer width dimension:

$$\begin{aligned} L_a &= 20.55 - 15 \times (0.007 - (-0.002) - 0.004) \\ &= 20.55 - 0.075 \\ &= 20.475 \end{aligned}$$

Note the code!

3.5. Grease Packing

Procedure for packing grease after cleaning bearings

A rapid rise in temperature may occur during initial running-in due to improper packing of grease. This can result in a long running-in period, or lead to seizure and bearing failure. Following proper procedures for packing grease and using the correct amount of grease deserves careful attention. Recommended procedures are as follows:

1. Pre-inspection

Check to ensure there is no foreign matter in the bearing interior. Bearings for high speed spindle shafts should be cleaned, degreased, and packed with grease. For other applications, remove any anti-corrosion agent adhering to interior surfaces of the bearings.

2. Grease dispensers

Use a grease dispenser, such as a plastic syringe for precision grease dispensing. If possible, use a dispenser that comes with a gauge for packing accurate amounts of grease.

3. Amount of grease

Recommended amounts of grease packing for precision bearings:

Angular contact ball bearings for high speed machine tool spindles:  $15\% \pm 2\%$  of internal space

Cylindrical roller bearings for high speed machine tool spindle:  $10\% \pm 2\%$  of internal space

Ball bearings for motors: 20% to 30% of internal space

Recommendation of grease amount for various bearing types and numbers is shown on Page 175.

Packing method for ball bearings

- (1) Pack grease evenly between the balls. If an outer ring guided cage is used, such as a phenolic resin cage, apply a light coating of grease on the guided surface.
- (2) Rotate the bearing by hand to spread grease evenly on the surfaces of the raceway, ball, and cage.

Packing method for cylindrical roller bearings

- (1) Coat about 80% of the grease amount evenly on roller rolling surface. Avoid putting too much grease on the cage bore. Grease on the cage bore is difficult to disperse during the running-in period, which can result in a rapid rise in temperature or a long running-in period.
- (2) Coat roller surfaces with a thin film of grease, including the roller end faces, roller cage contact points, and along the face edges of each cage pocket.
- (3) Using the remaining 20% of grease, apply a thin film of grease to the raceway surface of the outer ring.

Fig. 1.19 Grease Packed Angular Contact Ball Bearing

Fig. 1.20 Grease Packed Cylindrical Roller Bearing

4. Inspection after Mounting

4.1. Runout accuracy

Accurate mounting and related parts are indispensable to ensure precision and accuracy of the machine tool spindle.

- 1: Assembled bearing outer ring face runout with raceway for angular contact ball bearings.  
Adjust to 0.002 mm or less by tapping on the outer ring end face.
- 2: Variation of bearing outside surface generatrix inclination with outer ring reference face for angular contact ball bearings.  
Adjust to 0.005 mm or less tilting the locknut (see Fig. 1.21).

3: Concentricity of rear side housing 0.010 mm or less.

If these accuracies cannot be met, disassemble the bearings and check the accuracy of parts again.

Fig. 1.21 Tilting the Shaft Locknut

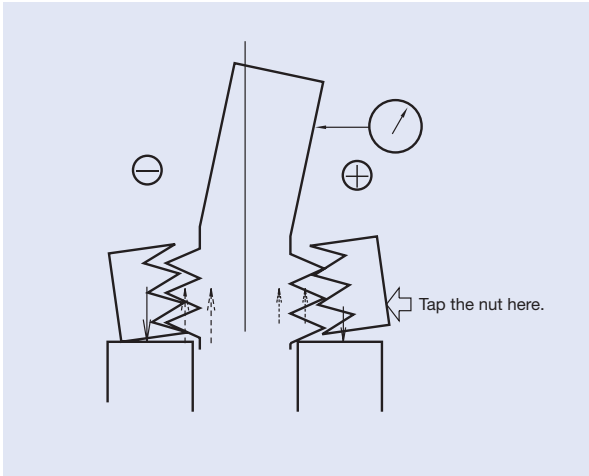

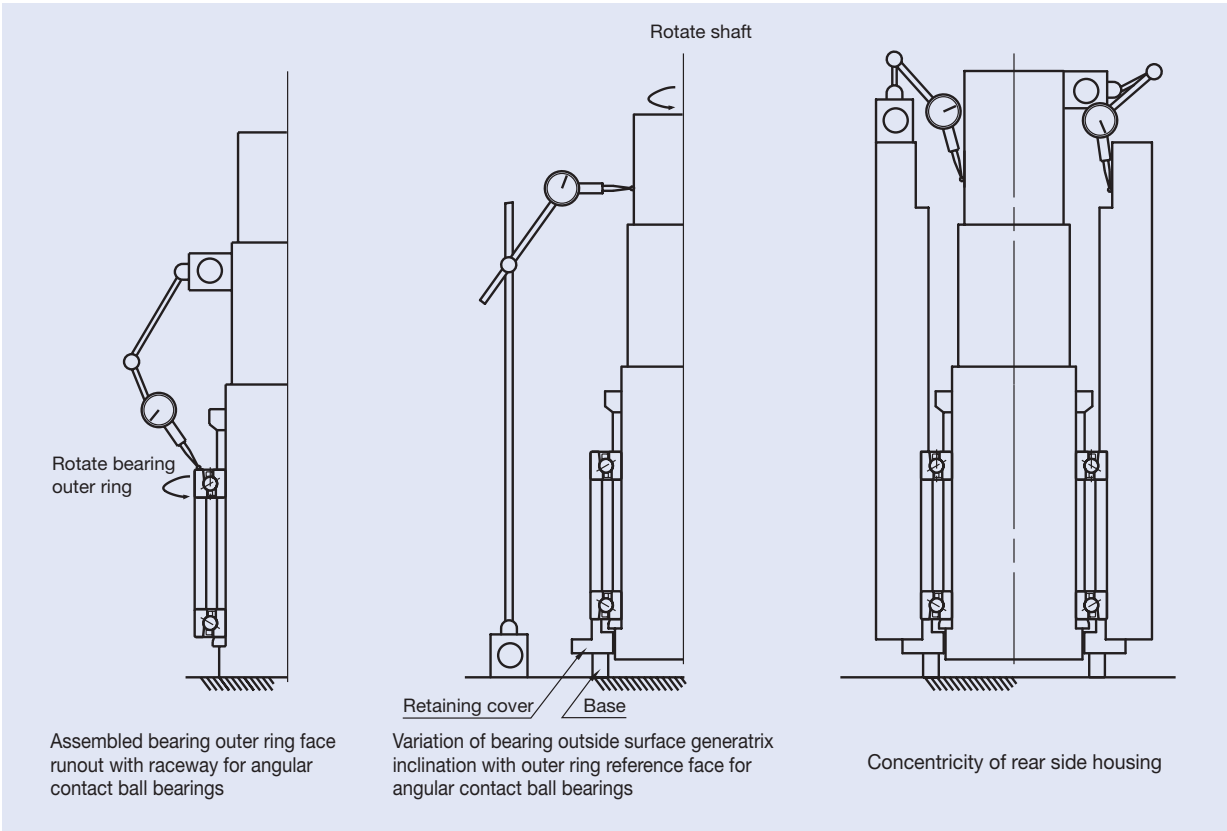

Fig. 1.22 Runout Accuracy of Machine Tool Spindle

4.2. Control of Preload after Mounting of Bearings

If the preload of rolling bearing is set larger, the rigidity of bearing is increased, but heat generation is also increased, and in extreme cases, seizure may occur. Therefore, it is necessary to control optimum preload carefully in response to operating condition. Measuring method of preload for angular contact ball bearing is introduced below. For the preload of cylindrical roller bearing, it is recommended to control by using a GN gauge in mounting process (see Page 202).

Measuring of preload for angular contact ball bearings

There are three methods for checking preload of bearings after mounting onto the main shaft: starting torque method, thrust static rigidity method, and natural frequency method. Features of these methods are summarized in Table 1.3.

Table 1.3

	Starting torque method	Thrust static rigidity method	Natural frequency method
Advantage	Used for heavy preload, If starting torque is high, measurement error is small.	Used for light preload	Measurement accuracy is high. Good repeatability.
Disadvantage	Not good for light preload. If starting torque is small, variation of measurement is large.	Not good for heavy preload. Loading equipment is too large scale. Affected easily by deformation of contact part other than bearing.	Influence of spindle fixing condition should not be ignored.

(1) Starting torque method

[Characteristic]  
High speed main shaft spindle bearings are often used with light preload so that starting torque is low and measurement error is large.

[Method]  
Starting torque is obtained mainly by measuring tangential force (see Fig. 1.23).  
Preload is obtained from the relationship between measured starting torque and preload (see Fig. 1.24).

When oil film formation in rolling contact area is unstable during measurement, sticking occurs (Rotation does not start even under tangential force and rotation starts suddenly when tangential force is increased gradually). The torque at such occasion tends to be higher than predicted calculated torque so that the excessive measurement result needs to be excluded.

Fig. 1.23 Starting Torque Method

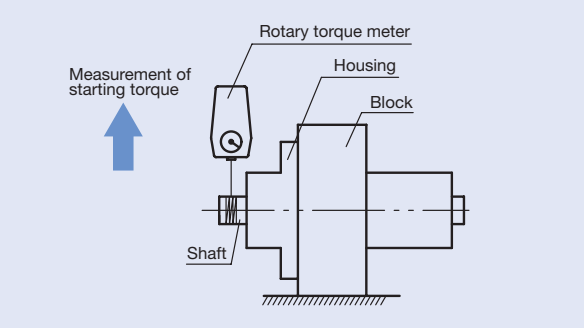

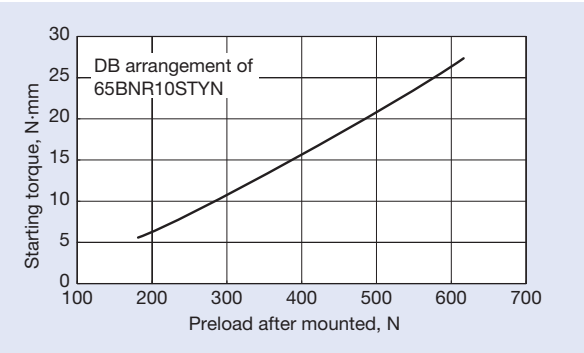

Fig. 1.24 Relation between Starting Torque and Preload

(2) Thrust static rigidity method

[Characteristic]  
When axial rigidity of the bearing is high, axial force necessary for measurement becomes very high and loading equipment is necessary (Example: If axial rigidity is 200N/μm, 2 000N load is needed to generate 10 μm displacement). When measurement load is large, besides elastic deformation of bearing interior, effect of surface deformation and elastic deformation of other related parts are added. Measured rigidity tends to be lower than theoretical value and error often occurs.

[Method]  
Thrust load is applied to shaft and its axial displacement is measured for obtaining preload (see Figs. 1.25 and 1.26).

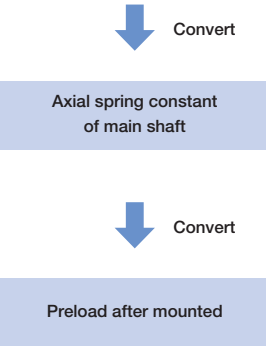

(3) Natural frequency method

[Characteristic]  
Measuring sensitivity is the highest and repeatability is good, but tend to be affected by spindle fixing condition.

[Method]  
Shaft is vibrated in an axial direction and resonance frequency of shaft is measured at the same time. Preload can be obtained by the resonance frequency (see Figs. 1.27 and 1.28).

Measurement of resonance frequency ( $F_z$ ) for main shaft in axial direction

$$F_z = \frac{1}{2\pi} \sqrt{\frac{K_a}{m}} \times 1\,000$$

$K_a$  : Axial spring constant of bearing (N/μm)  
 $F_z$  : Resonance frequency (Hz)  
 $m$  : Mass of rotating body (kg)

Fig. 1.25 Thrust Static Rigidity Method

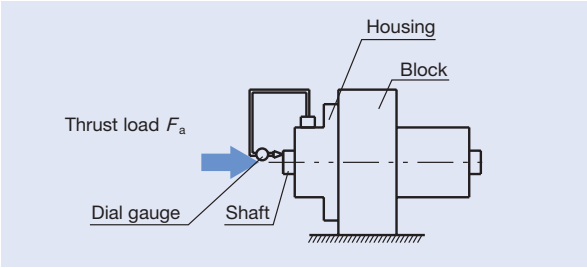

Fig. 1.26 Relation between Axial Displacement and Preload

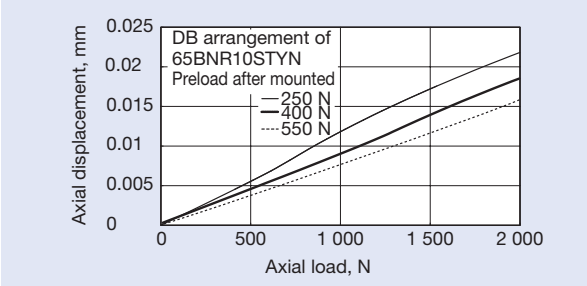

Fig. 1.27 Natural Frequency Method

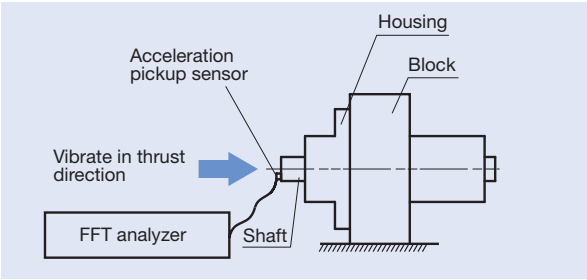

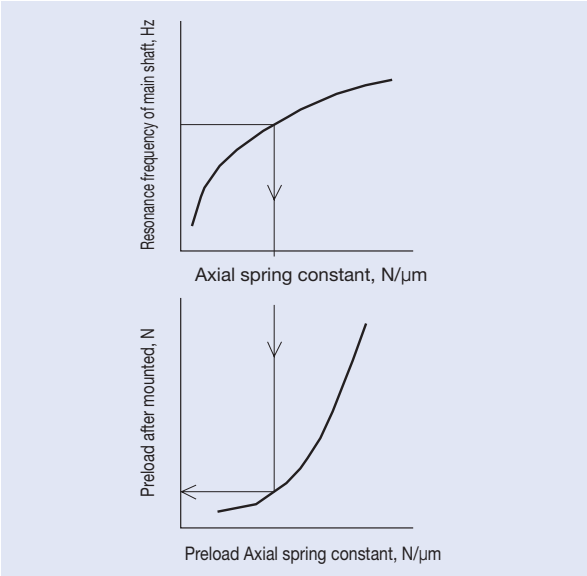

Fig. 1.28 Relation between Resonance Frequency of Main Shaft and Spring Constant

Operating Inspection

After mounting has been completed, a test run should be conducted to determine if the bearing has been mounted correctly. Small equipment may be manually operated to assure that they rotate smoothly. Items to be checked include sticking due to foreign matter, visible flaws, uneven torque caused by improper mounting, or an improper mounting surface. Other items include excessive torque caused by an inadequate clearance, mounting errors, or seal friction.

If there are no abnormalities, then a powered test run can be started. For high-speed equipment, perform running-in procedures before a powered test run (Pages 212-213). A powered test run should be started slowly without load. Make close observations to determine whether or not abnormalities exist. If everything seems satisfactory, then gradually increase the speed, load, etc., until normal operating conditions are reached.

During a test run operation, check for abnormal noise, excessive rise of bearing temperature, leakage and contamination of lubricants, etc. If any abnormality is found, stop the test run immediately and inspect the machinery. If necessary, the bearing should be dismounted for examination as well. Although the temperature of the outside surface of the housing can generally help determine bearing temperature, it is

better to directly measure the temperature of the outer ring using oil holes for access. The bearing temperature should rise gradually to a steady level within one or two hours after operation starts. If the bearing experiences trouble, or if an error was made in mounting, the bearing temperature may increase rapidly and become abnormally high. The cause of this abnormal temperature may be an excessive amount of lubricant, insufficient bearing clearance, incorrect mounting, or excessive friction of the seals. In the case of high speed operations, an incorrect selection of bearing type or lubricating method may also cause an abnormal temperature rise.

Bearing noise can be checked with an acoustic or other instruments. Abnormal conditions are indicated by a loud metallic sound, or other irregular noise. Possible causes include incorrect lubrication, poor alignment of the shaft and housing, or the entry of foreign matter into the bearing. Possible causes and countermeasures for irregularities are listed in Table 2.1.

Table 2.1 Cause and Countermeasures for Operating Irregularities

Irregularities		Possible cause	Countermeasures
Noise	Loud metallic sound (')	Abnormal load	Improve the fit, internal clearance, preload position of housing shoulder, etc.
		Incorrect mounting	Improve the machining accuracy and alignment of shaft and housing, accuracy of mounting method.
		Insufficient or improper lubricant	Replenish the lubricant or select another lubricant.
		Contact of rotating parts	Modify the labyrinth seal, etc.
	Loud regular sound	Dents generated by foreign matter, corrosion, flaws, or scratches on raceways	Replace or clean the bearing, improve the seals, and use clean lubricant.
		Brinelling	Replace the bearing, and use care when handling bearings.
		Flaking on raceway	Replace the bearing.
	Irregular sound	Excessive clearance	Improve the fit, clearance, and preload.
		Penetration of foreign particles	Replace or clean the bearing, improve the seals, and use clean lubricant.
		Flaws or flaking on balls	Replace the bearing.
Abnormal temperature rise		Excessive amount of lubricant	Reduce amount of lubricant, or select stiffer grease.
		Insufficient or improper lubricant	Replenish lubricant or select a better one.
		Abnormal load	Improve the fit, internal clearance, preload, or position of housing shoulder.
		Incorrect mounting	Improve the machining accuracy and alignment of the shaft and housing, accuracy of mounting, or mounting method.
		Creep on fitted surface, excessive seal friction	Correct the seals, replace the bearing, or correct the fitting or mounting.
Vibration (Radial runout of shaft)		Brinelling	Replace the bearing and use care when handling bearing.
		Flaking	Replace the bearing.
		Incorrect mounting	Correct the squareness between the shaft and housing shoulder or side of spacer.
		Penetration of foreign particles	Replace or clean the bearing, improve the seals.
Leakage or discoloration of lubricant		Too much lubricant. Penetration by foreign matter or abrasion chips	Reduce the amount of lubricant, select a stiffer grease. Replace the bearing or lubricant. Clean the housing and adjacent parts.

**Note** (') Squeaking may arise from grease lubricated ball bearings or cylindrical roller bearings (medium to large sized). This is especially true during winter when temperatures are low. In general, even though squeaking may occur, the bearing temperature will not rise, leaving fatigue or grease life unaffected. Consequently, such a bearing can continue to be used. If you concerns regarding squeaking noise, please contact NSK.

Preparations

The following running-in procedures are necessary after properly mounting bearings.

■ Balance of Shaft and Assembly

Any unbalance of rotating components will cause repeated stress or excessive vibrations due to centrifugal force. This is especially true for spindles, which are operated at a  $d_m n$  value of 1 000 000 or higher. Therefore, it is imperative that both the shaft assembly are well balanced.

■ Spindle Assembly

Spindle assemblies with a V-belt drive should have misalignment of the spindle pulley center and motor pully center corrected to a target of 0.1 mm or less. Coupling joints should have misalignment of the spindle shaft center and motor shaft center corrected to a target of 0.01 mm or less.

Initial Running in Methods

If operating speed is suddenly increased after the bearings are mounted, the operating temperature will rise abruptly and bearing failure may occur. Grease lubricated bearings, especially, require that you follow proper running-in procedures. Increase operating speed gradually to completely orient the initially filled grease on each contact surface raceway. Running in should be conducted under ambient temperature conditions (15°C to 25°C) while monitoring bearing temperature.

Maximum operating temperature of the spindle housing exterior should be targeted at about 50°C. Do not to exceed 55°C. If a rapid temperature increase occurs, temporarily stop the running-in process or decelerate to lower the temperature. Some spindle assemblies incorporate both cylindrical roller bearings and angular contact ball bearings. Since cylindrical roller bearings tend to experience a more rapid temperature increase in comparison with ball bearings, timing of speed increases must be set to correspond with the roller bearings.

[Caution]

Spindle assemblies operating under oil mist and oil-air lubricating conditions risk a sudden temperature rise at initial operation, or after the spindle assembly has not been operated for a long time. Excess oil that has collected in the oil lines of the lubrication system may suddenly flood the bearing interior, causing a temperature spike. Performing running-in procedures for bearings with these lubricating systems require much less time than grease-based systems, and are highly recommended.

(1) Continuous running-in procedure

[Feature]

Continuous running-in works by gradually increasing operating speed from the low speed zone. Although somewhat time consuming, this procedure helps machine operators to detect potential problems related to the main shaft, thus avoiding costly damage to the bearings.

[Method]

Maximum operating speed of the application is achieved by repeating several steps in a cycle.

Step 1. Begin at a reasonably low operating speed.

Step 2. Monitor for temperature rise.

Step 3. Stable temperature is reached.

Step 4. Continue incremental increases of operating speed.

Continue repeating the above cycle until an equilibrium temperature is reached at the maximum operating speed and divide it into ten stages to determine the target speed for each stage. Then, repeat the above cycle for one or two hours until the target speed is reached for that stage. Move up to the next stage and repeat the above cycle until you reach the next target speed.

Fig. 3.1 Temperature Change of Constant Speed Running-in Operation

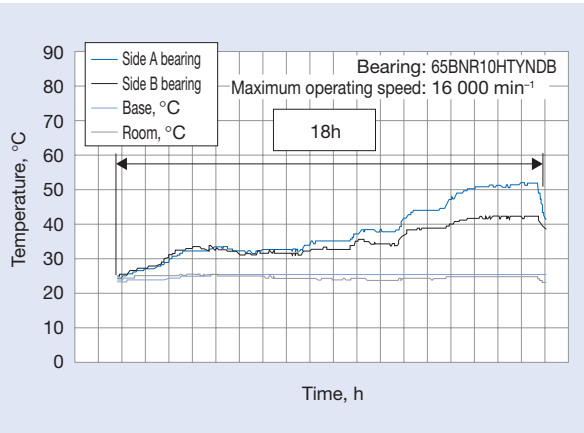

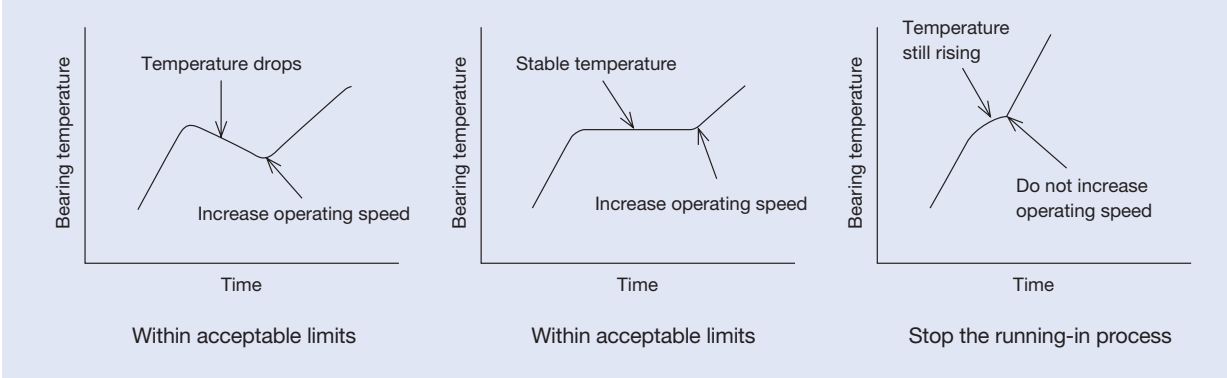

Fig. 3.2 Increase of Operating Speed Continuous Running in

Increase operating speed when temperature rise characteristics are within limits.

(2) Intermittent Running-in procedure

[Feature]

Intermittent Running in works by stopping operation and stabilizing temperatures before there is a rapid temperature rise, which is caused by a sudden supply of grease to the bearing interior during initial operation. This procedure allows us to shorten the amount of time required for running in. Procedures for intermittent running in vary from machine to machine and bearing arrangements. Be sure to confirm the bearing arrangement for each spindle application.

[Method]

First, take the maximum operating speed and divide it into eight or ten stages to determine the maximum target speed for each stage. Each stage is divided into 10 cycles that are approximately one minute long.

During each cycle, rapidly accelerate the spindle assembly to the target speed for the current stage decelerate back to zero. Repeat this cycle about 10 times. Move up to the next stage and repeat the above cycle 10 times for the target speed of that stage.

Fig. 3.3 shows temperature rise data for a bearing with a maximum operating speed of 16 000 min<sup>-1</sup>. The maximum speed was divided into 8 stages with 10 cycles each of rapid acceleration and deceleration. Fig. 3.4 shows an example of 1 cycle. And it is desirable to make it rotate slowly by about 500 min<sup>-1</sup> for 15 minutes, and to familiarize grease and before operating start. As for after an operation end, it is desirable to perform fixed operation about 1 hour at maximum speed.

Bearing Failure Diagnosis

- 1. Bearing Failure and Measures .....P216-219
- 2. Diagnosis with Sound and Vibration .....P220-225

Bearing Failure and Measures  
Diagnosis with Sound and Vibration

*Bearing Failure*      *Diagnosis*

Maintenance, Inspection and Correcting Irregularities

In order to maintain the original performance of a bearing for as long as possible, proper maintenance and inspection should be performed. If proper procedures are used, many bearing problems can be avoided and the reliability, productivity, and operating costs of the equipment containing the bearings are all improved. It is suggested that periodic maintenance be done following the procedure specified. This periodic maintenance encompasses the supervision of operating conditions, the supply or replacement of lubricants, and regular periodic inspection.

Items that should be regularly checked during operation include bearing noise, vibration, temperature, and lubrication. If an irregularity is found during operation, the cause should be determined and the proper corrective actions should be taken after referring to Table 2.1.

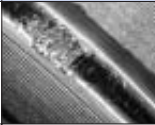

If necessary, the bearing should be dismounted and examined in detail.

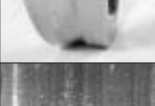

Bearing Failure and Measures

In general, if rolling bearings are used correctly they will survive to their predicted fatigue life.

However, they often fail prematurely due to avoidable mistakes. In contrast to fatigue life, this premature failure is caused by improper mounting, handling or lubrication, entry of foreign matter, or abnormal heat generation. For instance, the causes of rib scoring, as one example, are the use of improper lubricant, faulty lubricant system, entry of foreign matter, bearing mounting error, excessive deflection of the shaft, or any combination of these. Thus, it is difficult to determine the real cause of some premature failures. If all the conditions at that time of failure and previous to the time of failure are known, including the application, the operating conditions, and environment; then by studying the nature of the failure and its probable causes, the possibility of similar future failures can be reduced. The most frequent types of bearing failure, along with their causes and corrective actions, are listed in Table 1.1.

Table 1.1 Causes and Measures for Bearing Failures

Type of Failure	Irregularities	Photo	Probable Causes	Measures
Flaking	Flaking on one side of the raceway of radial bearing.		Abnormal axial load (sliding failure of free-side bearing).	When mounting the outer ring of free-side bearings, it should be fitted loosely, to allow axial expansion of the shaft.
	Flaking pattern inclined relative to the raceway in radial ball bearings Flaking near the edge of the raceway and rolling surface in roller bearing.		Improper mounting, bending of shaft, inadequate centering, inadequate tolerances for shaft and housing.	Use care in mounting and centering, select a bearing with a large clearance, and correct the squareness of shaft and housing shoulder.
	Flaking of raceway with same spacing as rolling element.		Large shock load during mounting, rusting while bearing is out of operation for prolonged period, mounting flaws of cylindrical roller bearings.	Use care in mounting and apply a rust preventative when machine operation is suspended for a long time.
	Premature flaking of raceway and rolling element.		Insufficient clearance, excessive load, improper lubrication, rust, etc.	Select proper fit, bearing clearance, and lubricant.
	Premature flaking of combined bearings.		Excessive preload.	Adjust the preload.
Scoring	Scoring or smearing between raceway and rolling surface.		Inadequate initial lubrication, excessively hard grease, high acceleration when starting operation.	Use a softer grease and avoid rapid acceleration.

Type of Failure	Irregularities	Photo	Probable Causes	Measures
Scoring	Scoring or smearing between the end face of the rollers and guide rib.		Inadequate lubrication, incorrect mounting and large axial load.	Select proper lubricant and modify the mounting.
Cracks	Crack in outer or inner ring.		Excessive shock load, excessive interference in fitting, poor shaft cylindricity, improper sleeve taper, large fillet radius, development of thermal cracks and increased flaking.	Examine the loading conditions, modify the fit of bearing and sleeve, improve accuracy in machining shaft and sleeve, collect fillet radius (the fillet radius must be smaller than the bearing chamber).
	Crack in rolling element or broken rib.		Increased flaking, shock applied to rib during mounting or dropped during handling.	Use care in mounting and handling a bearing.
	Fracture of cage.		Abnormal loading on the cage due to incorrect mounting. Improper lubrication	Correct mounting and examine the lubrication method and lubricant.
Indentations	Indentation on raceway with the same spacing as rolling element (Brinelling).		Shock load during mounting or excessive load when not rotating.	Use care in handling the bearing.
	Indentations on raceway and rolling elements.		Entry of foreign matter such as metallic particle and grit.	Clean the housing, improve the seals and use clean lubricant.
Abnormal wear	False brinelling (phenomenon similar to brinelling).		Vibration of the bearing without rotation when out of operation, such as during transport, or rocking motion of vibration.	Secure the shaft and housing, use oil as a lubricant and reduce vibration by applying preload.
	Fretting, Localized wear with reddish-brown wear dust at fitting surface.		Sliding wear at a minute gap in the fitting surface.	Increase interference and apply oil.
	Wearing on raceway, rolling elements, rib and cage.		Entry of foreign matter, incorrect lubrication and rust.	Improve sealing capabilities, clean the housing and use a clean lubricant.
	Creep, scoring wear at fitting surface.		Insufficient interference, insufficiently secured sleeve.	Modify the fitting and tighten the sleeve properly.
Seizure	Discoloration and melting of raceway, rolling elements and ribs.		Insufficient clearance, incorrect lubrication, or improper mounting.	Examine the fitting and internal clearance of a bearing, supply an adequate amount of proper lubricant and examine the mounting method and quality of related parts.
Corrosion and Rust	Corrosion and rust at bearing interior or fitting surface.		Condensation of water from the air, or fretting, entry of corrosive substance (especially varnish gas).	Store carefully when in a moist or hot climate, take rust prevention measures before removing from operations for a long time, and select proper varnish and grease.

Running Traces and Applied Loads

Remark: This table is not comprehensive. It lists only the more commonly occurring damages, causes, and locations.

Classification of sounds and vibrations

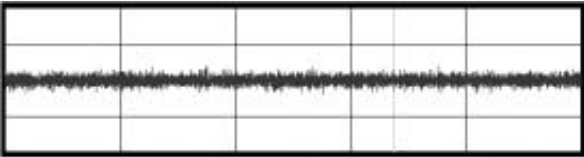

Sound and vibration accompany the rotation of rolling bearings. The tone and amplitude of such sound and vibration vary depending on the type of bearing, mounting conditions, operational conditions, etc. The sound and vibration of a rolling bearing can be classified under the following four chief categories and each category can be further classified into several sub-categories, as described in Table 2.1 below. Boundaries between groups are, however, not definite. Even if some types of sounds or vibrations are inherent in the bearings, the volume might be related to the manufacturing process, while some types of sounds or vibrations, even if they arise due to manufacturing,

cannot be eliminated even in normal conditions. By recording sounds and vibrations of a rotating machine and analyzing them, it is possible to infer the cause. As can be seen from figures on the next page, a mechanically normal bearing shows a stable waveform. However, a bearing with a scratch, for example, shows a waveform with wide swings indicating large-amplitude sounds at regular intervals. NSK produces Bearing Monitor NB-4, a vibration measuring monitor that can diagnose irregularities in a rotating machine, and the causes of the irregularities can be inferred using the NB-4 and recording equipment, such as a personal computer.

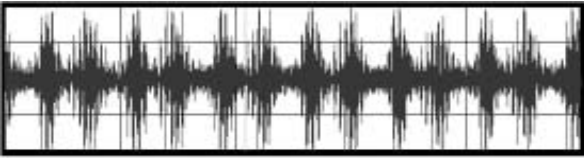

Table 2.1 Classification of sounds and vibrations in a rolling bearing

	sound		Vibration		Features
Structural	Race noise		Free vibration of raceway ring		Continuous noise, basic unavoidable noise which all bearings generate
	Click noise		Free vibration of raceway ring, free vibration of cage		Regular noise at a certain interval, large bearings and horizontal shaft, radial load and low rpm
	Squeal noise		Free vibration of raceway ring		Intermittent or continuous, mostly large cylindrical roller bearings, radial load, grease lubrication, at particular speed
	Cage noise	“CK” noise	Free vibration of cage		Regular noise at a certain interval, all bearing types generate it
		“CG” noise	Vibration of cage		Intermittent or continuous, lubrication with particular grease
		Tapping noise	Free vibration of cage		Certain interval, but a little irregular under radial load and during initial stage
	—		Rolling element passage vibration		Continuous, all bearing types under radial load
Manufacturing	Waviness noise		Vibration due to waviness	Inner ring	Continuous noise
				Outer ring	Continuous noise
				Rolling element	Continuous with rollers, occasional with balls
Handling	Flaw noise		Vibration due to flaw	Inner ring	Regular noise at a certain interval
				Outer ring	
				Rolling element	
	Contamination noise		Vibration due to contamination		Irregular
Others	Seal noise		Free vibration of a seal		Contact seal
	Lubricant noise		—		Irregular
	—		Runout	$f_r$	Continuous
				$f_c$	Continuous
				$f_r-2f_c$	Continuous

$n$ : Positive integer (1, 2, 3...)  
 $Z$ : Number of rolling elements  
 $f_{RIN}$ : Ring natural frequency in radial bending mode, Hz  
 $f_{MI}$ : Natural frequency in the mode of angular vibration in inertia of outer ring-spring system, Hz  
 $f_i$ : Rotation frequency of inner ring, Hz

Sound waveform of a normal bearing

Sound waveform of a scratched bearing

Vibration Measuring Equipment, Bearing Monitor NB-4 (See Page 128)

Generated frequency (frequency analysis)		FFT after envelope (basic No.)	Source	Measures
FFT of original wave				
Radial (angular) direction	Axial direction			
$f_{RIN} \cdot f_{MI}$	$f_{AIN} \cdot f_{AM}$	—	Selective resonance of waviness (rolling friction)	Improve rigidity around the bearings, appropriate radial clearance, high-viscosity lubricant, high-quality bearings
$f_{RIN} \cdot f_{MI}$ Natural frequency of cage	$f_{AIN} \cdot f_{AM}$	$Zf_c$	Collision of rolling elements with inner ring or cage	Reduce radial clearance, apply preload, high-viscosity oil
$(\approx f_{R2N} \cdot f_{R3N})$	—	?	Self-induced vibration caused by sliding friction at rolling surface	Reduce radial clearance, apply preload, change the grease, replace with countermeasured bearings
Natural frequency of cage		$f_c$	Collision of cage with rolling elements or rings	Apply preload, high-viscosity lubricant, reduce mounting error
Natural frequency of cage		?	Self-induced vibration caused by friction at cage guide surface	Change of grease brand, replace with countermeasured cage
Natural frequency of cage		$Zf_c$	Collision of cage and rolling element caused by grease resistance	Reduce radial clearance, apply preload, low-viscosity lubricant
$Zf_c$	—	—	Displacement of inner ring due to rolling element passage	Reduce radial clearance, apply preload
$nZf_i \pm f_r$ ( $nZ \pm 1$ peaks)	$nZf_i$ ( $nZ$ peaks)	—	Inner ring raceway waviness, irregularity of shaft exterior	High-quality bearings, improve shaft accuracy
$nZf_c$ ( $nZ \pm 1$ peaks)	$nZf_c$ ( $nZ$ peaks)	—	Outer ring raceway waviness, irregular bore of housing	High-quality bearings, improve housing bore accuracy
$2nf_b \pm f_c$ ( $2n$ peaks)	$2nf_b$ ( $2n$ peaks)	—	Rolling element waviness	High-quality bearings
$f_{RIN} \cdot f_{MI}$	$f_{AIN} \cdot f_{AM}$	$Zf_i$	Nicks, dents, rust, flaking on inner ring raceway	Replacement and careful bearing handling
		$Zf_c$	Nicks, dents, rust, flaking on inner ring raceway	Replacement and careful bearing handling
		$2f_b$	Nicks, dents, rust, flaking on rolling elements	Replacement and careful bearing handling
$f_{RIN} \cdot f_{MI}$	$f_{AIN} \cdot f_{AM}$	Irregular	Entry of dirt and debris	Washing, improve sealing
Natural frequency of seal		$(f_r)$	Self-induced vibration due to friction at seal contact area	Change the seal, change the grease
?	?	Irregular	Lubricant or lubricant bubbles crushed between rolling elements and raceways	Change the grease
$f_r$	—	—	Irregular inner ring cross-section	High-quality bearings
$f_c$	—	—	Ball variation in bearing, rolling elements non-equidistant	High-quality bearings
$f_r - 2f_c$	—	—	Non-linear vibration due to rigid variation by ball variation	High-quality bearings

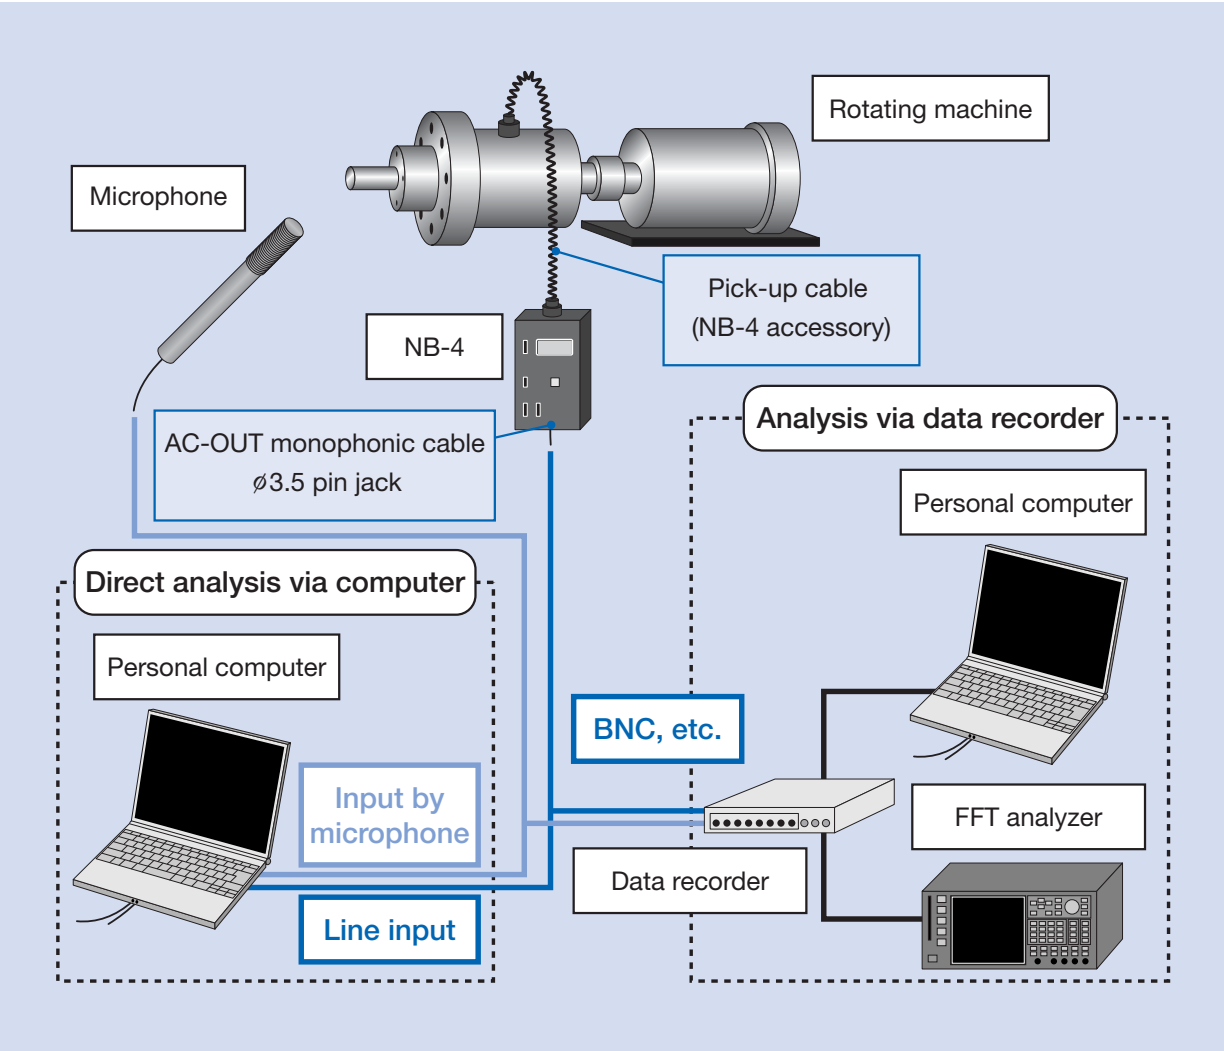

$f_c$ : Orbital revolution frequency of rolling elements, Hz  
 $f_{AIN}$ : Ring natural frequency in axial bending mode, Hz  
 $f_{AM}$ : Natural frequency in the mode of axial vibration in mass of outer ring-spring system, Hz  
 $f_i$ :  $f_i = f_r - f_c$ , Hz  
 $f_b$ : Rotation frequency of rolling element around its center, Hz

How to record sound and vibration waveforms

Through frequency analyses of sound or vibration of a rotating machine, it is possible to infer the cause of abnormal vibration. We will describe here how to record vibrations using Bearing Monitor NB-4 (see Page 128) and how to record sounds using

a microphone. Sounds and vibrations should be recorded under both normal and abnormal conditions, to determine the cause of irregularities.

Fig. 2.1 Configuration for recording sound and vibration waveforms

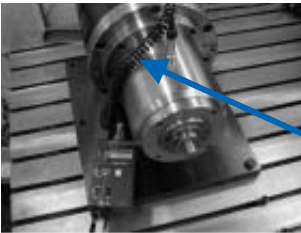

Cautions for recording sound and vibration waveforms

- Analyzing data after recording is easy provided the following precautions are taken.
- 1) Stop operation of nearby machines to cut off ambient noise and vibration.
  - 2) Collect sound and vibration data under both normal and abnormal conditions.
  - 3) Listen to a playback of recorded sounds to check for irregularities.
  - 4) Collect sound and vibration data while changing the number of rotations of the machine (for example, 100 min<sup>-1</sup>, 800 min<sup>-1</sup>, and 2 000 min<sup>-1</sup>).

How to record vibrations when recording the waveform directly by a computer

- Required equipment:
- Bearing Monitor NB-4
  - Personal computer (with line-input terminal and waveform recording software)
  - Monophonic cable for waveform data recording (ø3.5 pin jack at one end)

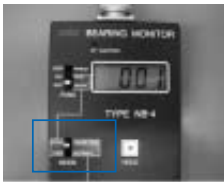

Connect the pick-up cable to Bearing Monitor NB-4 and then attach the pick-up terminal to the machine to be measured. To measure vibration, it is best to attach the pick-up terminal to a spot near a bearing in the machine.

Connect NB-4 (AC-OUT) and recording equipment (in the left picture, the microphone input of a personal computer\*) using a monophonic cable (ø3.5 pin-jack at NB-4 side).  
\*1 A microphone input terminal can be used as a substitute, although depending on the magnitude of vibration, it may not be able to handle input that falls outside of a given range.

Recording of rotating vibrations (NORMAL)

Recording of vibrations caused by a scratch inside a bearing (ENVELOPE)

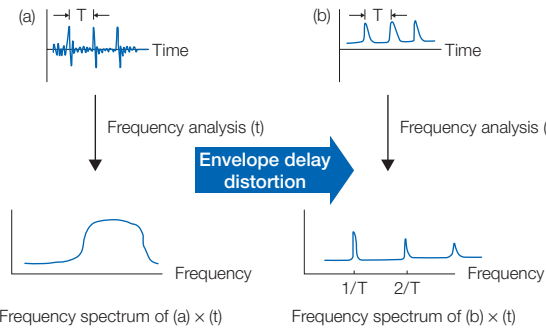

Set NB-4 to ACC-NORMAL when measuring rotation vibrations of a machine. Set NB-4 to ACC-ENVELOPE (envelope analysis\*) when measuring vibrations due to a scratch in a bearing.

Start recording vibration waveform data using audio recording software. Adjust recording level of the personal computer to maintain input signals within a given range. Recording for at least 20 seconds is recommended.

Save recorded vibration waveform data. (Be aware that some vibration data may be lost depending on the file format.)

Analyze recorded vibration waveform data to check for irregular vibration.

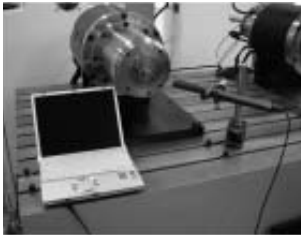

\*2 Envelope analysis  
Damage in the raceway surface or rolling element may produce impact vibration at regular intervals. In this case, FFT analysis of vibration waveforms cannot detect the frequency components generated by the damage. Under these circumstances, envelope analysis, which gives envelope delay distortion to original waveforms to analyze frequencies, can detect these frequency components. For envelope analysis, equipment needs to have an envelope processing function.

How to record sounds when recording directly by a computer

**Required equipment:**

- Microphone for measuring sound
- Personal computer (equipped with a microphone input terminal and audio recording software)

Connect a microphone to recording equipment. We recommend a microphone with frequency characteristics\*3 that effectively record the sounds of a machine. A microphone for measuring sound should be used because a microphone built into a personal computer is suitable for recording human voices but is often not appropriate for recording the sounds of a machine.

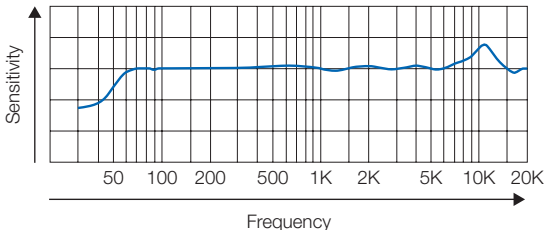

Keep the microphone at an appropriate distance from the rotating machine being inspected. (If too close, sounds of entangled air will be recorded, and if too distant, sound level will be too low.) It is recommended to stop operation of nearby machines to cut off the ambient noise, which makes it difficult to analyze recorded noise. Use a unidirectional microphone, if available, to cut off ambient noises.

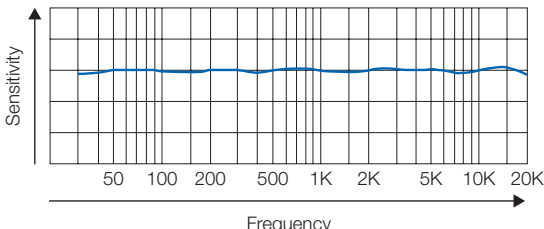

**\*3 Microphone frequency characteristics**

Frequency characteristics vary by type of microphone. For example, at 60Hz or less, the microphone (see Fig. 2.2) exhibits low sensitivity while the other microphone (see Fig. 2.3) exhibits stable characteristics for maintaining good sensitivity across a wide range of frequency bands. Therefore, the microphone Fig. 2.3 is suitable for measuring sounds of a machine due to its stable characteristics across a wide range of frequency bands.

**Fig. 2.2**

**Fig. 2.3**

Start recording with recording equipment. Adjust recording level of the personal computer to maintain input signals within a given range.

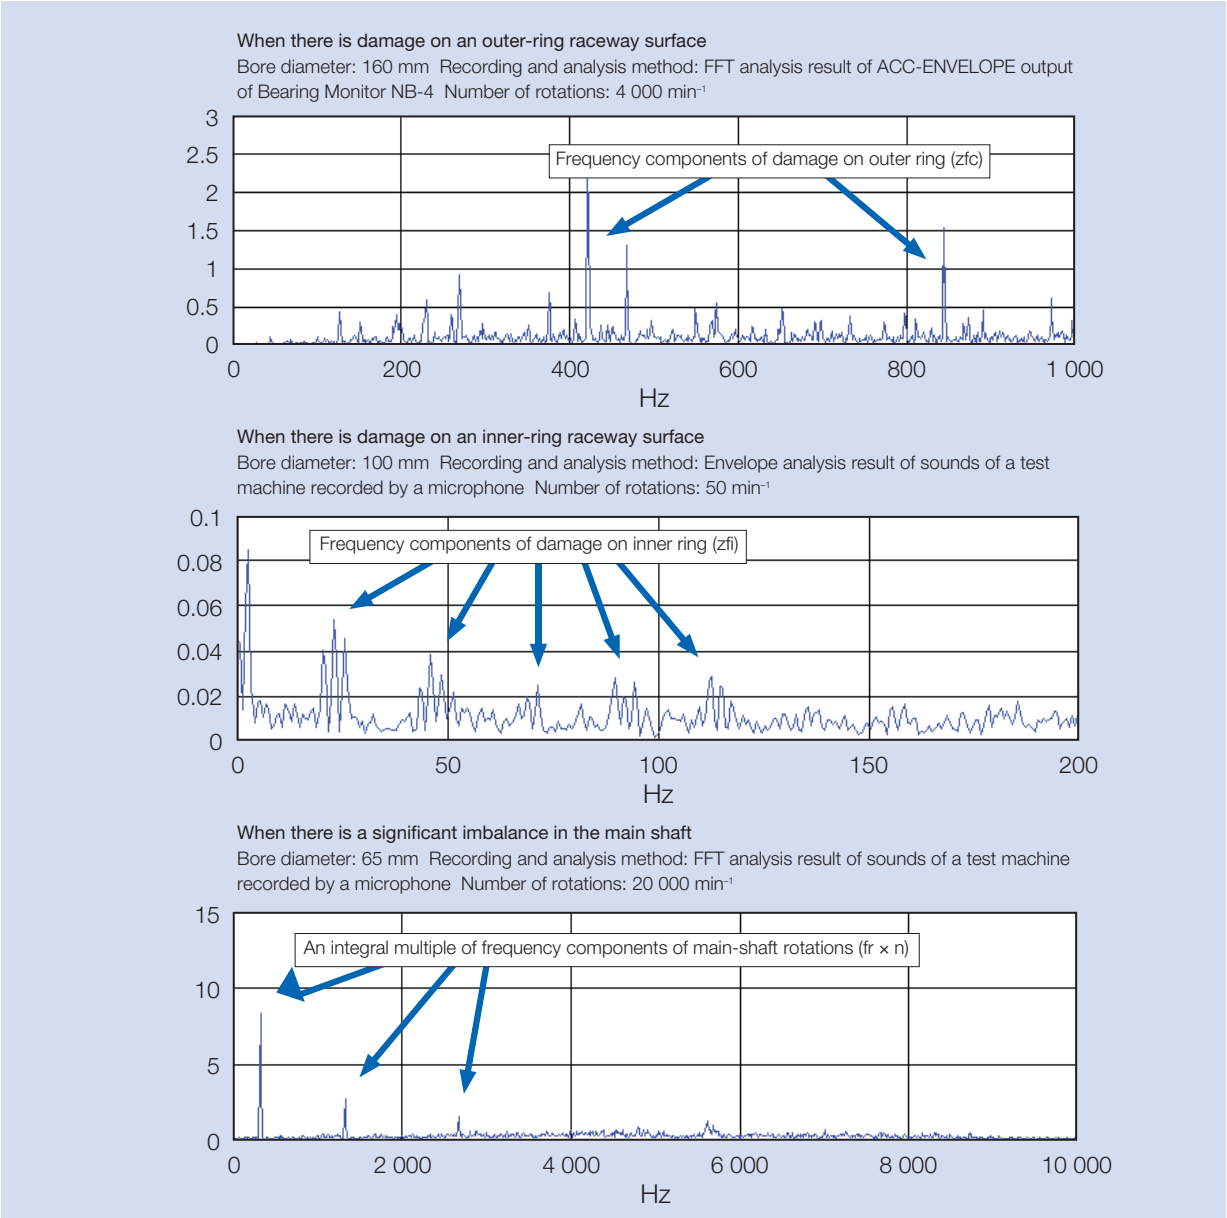

Save recorded sound data. (Be aware that some vibration data may be lost depending on the file format.)

Listen to a playback of recorded sounds to check for irregular noise.

Sounds recorded in this way and saved as a WAV file can be frequency-analyzed by using commercially available FFT software. Vibration or sound frequencies associated with damage such as scratching or waviness on the bearing raceway surface can be obtained as seen in Fig 2.4. When these frequency components are found as a result of frequency analysis conducted with FFT software, the bearing surface may be damaged. Upon request,

NSK will be able to analyze sounds stored as a WAV file. When such a request is made, NSK will need recorded sounds under both normal and abnormal conditions. Note that frequency analysis of sounds and vibration waveforms of a rotating machine may not be possible (Note that frequency analysis of sounds and vibration waveforms of a rotating machine may not be possible) when the recording conditions are not sufficiently fulfilled.

Method of Measuring Axial Clearance of Combined Angular Contact Ball Bearings

In the case of a DB arrangement, place the bearing without the inner-ring spacer on the cradle as described in the figure below, and apply measuring load to the inner ring. After the bearing is sufficiently stabilized, set the dial gauge to zero.

Next, after removing the outer-ring spacer, place the bearing with the inner-ring spacer on the cradle and apply measuring load in the same way as above. The reading of the dial gauge this time indicates the axial clearance. A positive reading signifies a CA clearance (clearance in the axial direction), and a negative reading shows a CP clearance, which generates preload.

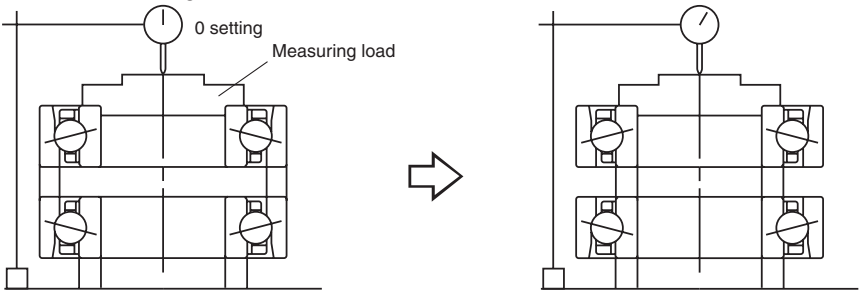

In the case of a DF arrangement, axial clearance is measured as with a DB arrangement, though locations of spacers and cradles are different.

In the case of single-row arrangement, the value of a double-row arrangement can be figured by adding together each value.

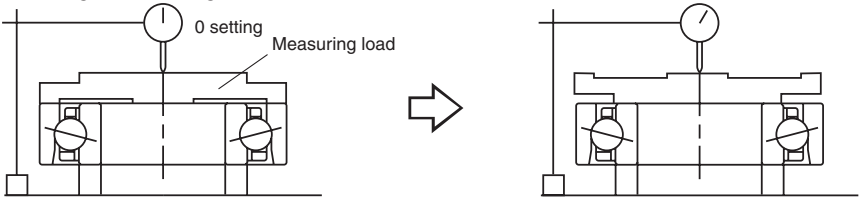

For measuring load, refer to Table 4.1 in Page 155.

DB arrangement

In the case of two-row arrangement

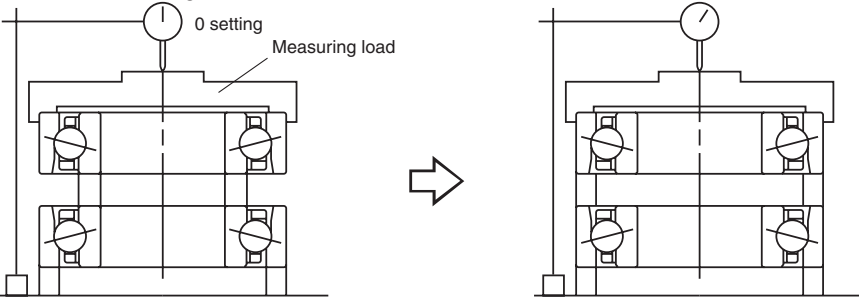

In the case of single-row arrangement

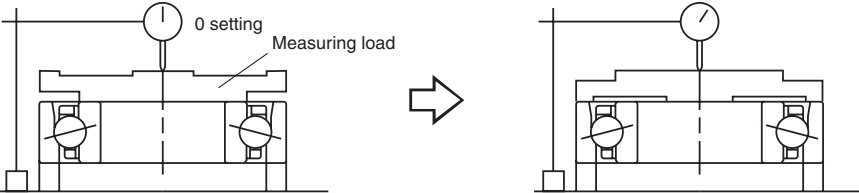

DF arrangement

In the case of two-row arrangement

In the case of single-row arrangement
